# Journal of the Society of Chemical Industry.

## INDEX OF VOL. IX.—1890.

### INDEX OF AUTHORS' NAMES.

N.B.—In this Index, (P) indicates that the matter referred to is an abstract of a Patent.

	PAGE		PAGE
<b>A</b>			
Abadie, A. Mills for Paper Making (P) .....	321	Amagat, E. H., and Jean, F. Optical Analysis of Oils and Butters .....	218
Abegg, R. Amidochrysene .....	600	Amat, L. Qualitative Distinction between Phosphite and Pyrophosphite of Lead .....	898
Abel, Sir F. A. Smokeless Explosives .....	325	Ambler, A. See Eastwood .....	610
Abel, F. A., and Dewar, J. Manufacture of Explosives (P) ..	764	Ambler, A. S. and F. Washing Wool and Animal Fibres (P) ..	856
Manufacture of Explosives (P) .....	765	American Ammonia Manufacturing Company. Obtaining Ammonia from Atmospheric Nitrogen (P) .....	392
Abel, Sir F. A., Dewar, J., and Anderson, W. Manufacture of Explosives and Cartridges therefrom (P) .....	893	Amoroso, F. F. Burning Liquid Fuel in Furnaces (P) .....	596
Abney, W. M. W. On the Grease Spot and Sector Photometers ..	722	Anderylini, P. Derivatives of Cantharidine .....	615
Actiengesellschaft für Anilin Fab. Green and Violet Colouring Matters (P) .....	386	Anderson, W. Apparatus for Purifying Water (P) .....	818
Orange Yellow Colouring Matters .....	1032	See Abel .....	893
Production of Azo-Colours (P) .....	385	Andre. See Berthelot .....	1069
Production of Mixed Azo-Colours (P) .....	386	André, G. Compounds of Mercury Chloride with Ammonia ..	647
Aceton, G. H. Assimilation of Carbon by Green Plants .....	634	Andre, O. Cleaning Filters (P) .....	379
Adair, J. Apparatus for Manufacture of Bread (P) .....	538	Andrews, L. W. Volumetric Determination of Combined Sulphuric Acid .....	328
Adant, G. Apparatus for Manufacture of Sugar (P) .....	528	Andrews, T. The Passive State of Iron and Steel (illus.) .....	951
Addison, P. L. Cleator Iron Company's Barytes and Umber Mines and Mills .....	953	Andrews, W. C. Apparatus for Purification of Gas (P) .....	797
Adgie, W. See Yeaton .....	797	Purification of Heating and Illuminating Gas (P) .....	797
Aerated Fuel Co. Furnaces for Utilising Hydrocarbon as Fuel (P) .....	49	Andria, M. N. d'. Treating Liquid Acid Residues (P) .....	860
Ahrens, F. B. Crystalline Veratrine .....	1060	Angell, A. Discussion on London Sewerage and Sewage .....	96
Aignan, A. Adulteration of French Turpentine Oil .....	330	Angus, R., and G. Craig. Washes for Animals (P) .....	813
Adulteration of Linseed Oil .....	903	Ankersmit, H. I. See Pietet .....	280
Aikman, C. M. Uses and Sources of Nitrogen in Agriculture ..	631	Anschütz, R., and Schultz, G. Action of Sulphur on certain Primary Aromatic Amines .....	49
Alexander, L. See Jones (P) .....	169	Anyon, T. Composition of Soap (P) .....	952
Alexander, P. H. Secondary Batteries (P) .....	521	Appert and Heurivaux. Devitrification of Glass .....	293
Secondary Batteries, and Plates therefor (P) .....	520	Appleberg, J. T. Purifying and Preserving Milk (P) .....	641
Alkaline Reduction Syndicate, The, and Cunningham, A. B. Recovery of Soda from Slags .....	519	Appleton, D. See Hopkinson .....	952
Treatment of Zinc Ores (P) .....	741	Appletree, I. Substitute for Ivory (P) .....	199
Alkier, F. C. Recovering Substances from Waste Waters of Paper Manufacture (P) .....	510	Arachequesne, E. Estimation of Acetone by Iodoform .....	660
Allain, E. H. Burner for Combustible Liquids (P) .....	728	Archbold, G. Manufacture of Iron and Steel (P) .....	195
Allan, J. See MacIvor .....	630	Archbutt, L. Determination of Sulphur in Iron and Steel ..	25
Allen, A. Discussion on Producing "Green-Mordanted" Wool ..	60	Discussion on Bacteriological Research .....	30
Allen, A. H. Commercial Cresylic Acid .....	141	Discussion on Determination of Sulphur in Iron and Steel ..	27
Discussion on Cresosoting Agents .....	1009	Speech at Annual Dinner .....	721
Discussion on Cresylic Acid .....	143	Archbutt, L., and Deeley, R. M. Softening Water (P) .....	406
Discussion on Diazotype Process .....	1004	Arche, A. See Eisemann .....	385
Discussion on Tempering Steel .....	114, 145	Archer, J. Doctors for Printing Textile Fabrics (P) .....	500
Allen, G. Composition of Soap (P) .....	879	Armour, J. and H. Retorts for Distilling Shale (P) .....	488
Allen, G. W., and Bowers, H. J. A. Apparatus for Purifying Water (P) .....	727	Armstrong, H. E. Oxidation of Turpentine in Sunlight .....	819
Allen and Tollens. Xylose and Gum from Straw .....	527	Armstrong, H. E., and Wympe, W. P. Action of Potash on Naphthalene-1:3-Disulphonic Acid .....	803
Alley, S. Apparatus for Treating Metallic Ores (P) .....	726	Constitution of the Tri-derivatives of Naphthalene ..	282, 283, 739
Rotating Furnaces for Calcining Ores (P) .....	1041	Influence of Certain Radicles on Formation of Disulphonic Acids .....	802
Allison, H. J. Galvanic Batteries (P) .....	1106	Arnand, J. Treatment of Ramie .....	760
Alsberg, M. Producing Minium (P) .....	954	Arnand. Digitalin and Taughinin .....	324
Alsberge, J. J. Manufacture of Chlorine (P) .....	623	Researches on Crystallised Digitalin .....	323
Alt, H. Gravimetric Determination of Thiocyanates .....	328	Arnfield, T. O. Apparatus for Dyeing and Treating Yarn (P) ..	805
Alt, H., and Schulze, J. Separation of Zinc and Nickel .....	328	Artmann, A., and Kufek, H. W. Production of Disinfectants (P) .....	1144
Alzurgary, J. B. A New Metallurgical Dry Process (P) .....	1041	Asboth, A. v. Artificial Cryolite and Dissociation of Aluminium Fluoride .....	945
Furnace for Refining Metals (P) .....	950	Detection of Cotton-Seed Oil in Lard .....	418
Insecticide for Trees and Plants (P) .....	201	Development of Hungarian Spirit Manufacture .....	102
Amagat, E. H. Alteration of Coefficient of Compressibility of Glass .....	862	Aschan, O. Acids of Low Carbon Density in Baku Petroleum ..	597

	PAGE		PAGE
Aseongh, J. Glazing, Antiseptic, and Washing Compounds (P).....	68	Baummann, T. Nigrisine.....	611
See Williams.....	886	Baume, M. J. D. A. de la. See Rousseau.....	757
Ashton, R. Preparing Colours for Making Writing Inks (P).....	857	Bauer, R. W. Mannring on Soil Analysis.....	490
Ashton, W. H. See McCarty.....	296	Baur, A. Artificial Musk.....	961
Ashwell, S. R. See Oswald.....	944	Producing a Substitute for Musk (P).....	545
Ashworth, A. Production of an Indigo Vat (P).....	939	Baxter, J., and Muter, J. Filtering and Filter Presses (P).....	593
Ashworth, J., and others. Apparatus for Dyeing Yarn (P).....	939	Bayer, K. J. Analysis of Sodium Aluminate.....	823
Astrop, W. Treating the Solid Portions of Sewage (P).....	539	Bayley, T. A Pocket-Book for Pharmacists, Medical Practitioners, Students, &c.....	423
Atkins, G. J. Apparatus for Separating Metals from Ores Electrically (P).....	742	Beach, F. Acid Fixing Bath.....	892
Atterberg, A. Gunning's Modification of Kjeldahl's Method of Estimating Nitrogen.....	825	Bechaup, A. The Phenomenon of Coagulation.....	1073
Aubin, E., and Quenot, J. Determination of Nitrogen in Manures.....	773	Bechi, E. Presence of Boric Acid in Plants.....	635
Auer-Schollinger. See Steiger.....	878	Beck, Discussion on Homo-Grown Sugar.....	157
Auge, E. Manufacture of Soda Alum (P).....	510, 859	Becker, H. A. Conversion of Crude Iron (P).....	627
On Soda Alum.....	858	Beckurts, H. Brucine.....	965
Auger, V. See Behal.....	289	Strychnine.....	965
		See Holst.....	978
<b>B</b>			
Babeock, B. F. See Greenway.....	298	Bedford, J. E. Apparatus for Production of Colouring Matters (P).....	385
Baherresses, F. New Porcelain and Glass Colours and Fixation thereof.....	943	Manufacture of Colouring Matters (P).....	497
Bach, C. Benzoxanthranol.....	1027	Bedson, P. P. Apparatus for Determining Carbonic Anhydride in the Air.....	1109
Badische Anilin und Soda Fabrik. Colouring Matters for Dyeing and Printing (P).....	1124	Apparatus for Gas Analysis.....	261
Colouring Matters of the Oxycetone Group (P).....	457	Discussion on Egyptian Salt.....	1109
Colouring Matter of the Oxycetone Group (P).....	609	Discussion on Estimating Tannin.....	261
Producing Coloured Compounds of Gallicetophenone on Fibres (P).....	500	Behal, A., and Auger, V. A New Class of Diacetones.....	280
Production of Colouring Matters (P).....	893	Beilby, G. Discussion on Manufacture of Phosphorus.....	165
Production of Disazo Colouring Matters (P).....	854	Discussion on Moisture in Paper Pulp.....	166
Baeyer, A., and Lohr, R. On Paramidotriphenylcarbinol.....	951	Beilby, G. T. See Young.....	278
Bailey, G. H. Discussion on Estimation of Arsenic Acid.....	159	Bein, S. Action of Fatty Substances on Gunpowder.....	762
Discussion on Sewage Purification.....	1106	Determination of Detonating Point of Explosives.....	214
Discussion on Technical Education Act, 1889.....	259, 260	Belitski, L. Ferrie Oxalate as a Reducer.....	413
Baird, A. and M. B. See Rose.....	486	Bell, C. R. E. Manufacture of Matches (P).....	414
Baker, C., and Crane, W. E. Filtering Oil (P).....	1046	Bell, Sir L. Evaporating Brine, &c. (P).....	67
Bakhuys-Roozeboom, H. W. Compounds of the Alkali Metals with Ammonia.....	507	Presidential Address at Ninth Annual Meeting.....	691
Bale, F. Obtaining Ammonia, Chlorine, and Hydrochloric Acid from Ammonium Chloride (P).....	861	Speech at Annual Dinner.....	718, 720
Ballantyne, H. Discussion on Revision of Constants.....	591	Bell, T. Lining Barrels to Resist Acids (P).....	519
See Thomson.....	588	Beloe, C. H. Purification of Sewage (P).....	97
Ballard, E. G. A New Actinometer (illus.).....	469	Beloe, C. H., and Candy, F. Purification and Filtration of Sewage (P).....	882
Bamberg, G. Obtaining Aluminium (P).....	741	Belstein, F., and Grosset, T. Determination of Free Sulphuric Acid in Aluminium Sulphate.....	416
Obtaining Alloys of Aluminium (P).....	741	Bendel, H. See Spilker.....	319
Bamberger, E. Hydrogenised Naphthylamines.....	494	Benedikt, R. Schmidt's Process for Converting Oleic Acid into Solid Fatty Acids.....	658
Bamberger, E., and Bortf, F. Aromatic $\alpha$ -Tetrahydronaphthol.....	493	Benedikt, R., and Bamberger, M. Quantitative Reaction for Lignin (illus.).....	1156
Bamberger, E., and Burgdorf, C. On Amidochrysene.....	605	Bengough, W. W. Evaporating Apparatus (P).....	1023
Bamberger, E., and Fiehn, W. Relation between the Physiological Properties and Constitution of Hydro-bases.....	887	Bertz, E., and others. Scouring Textile Fabrics (P).....	388
Bamberger, E., and Kitchelt, M. Alicyclic and Aromatic Tetrahydro- $\beta$ -Naphthylamine.....	602	Berend, L., and Stoehr, C. Brucine.....	1146
Aromatic Tetrahydro- $\beta$ -Naphthol.....	603	Bergel, A. Ratio between Electric and Thermal Conductivities of Metals.....	520
Bamberger, E., and Lohr, W. Alicyclic $\beta$ -Tetrahydronaphthol and Secondary Ring Alcohols.....	493	Berth, A. Aerating and Purifying Beer Worts (P).....	293
Bamberger, E., and Strasser, L. Fichtelite.....	274	Bergmann, E. Production of Cyanides (P).....	861
Bamberger, M. Analysis of Resins and Balsams.....	659	Beringer, C. and J. J. A Text-book of Assaying.....	117
See Benedikt.....	1156	Bernard, C. E. Reducing Agent for Treating Metallic Bodies (P).....	1135
Bang, I., and RuEn, A. Separating Tin from other Metals (P).....	950	Bernays, J. Discussion on Tempering Steel.....	115
Bang, I. A. F., and Ruffin, M. C. A. Separation of Tin from Scrap and Metals (P).....	1135	Bernhofer. Cements which stand Frost.....	511
Barbet, E. A. Process and Apparatus for Rectifying Alcohol (P).....	318	Bernstein, A. Electric Glow Lamps (P).....	868
Bardet, G. Comparative Activity of Different Digitalins.....	324	Bernthsen, A. $\alpha$ -Naphthylamine and $\alpha$ -Naphthol- $\beta$ -disulphonic Acid.....	491
Barnes, J. Yeast Cakes (P).....	319	On Naphtholsulphonosulphonic and $\alpha$ -Naphtholsulphamido-sulphonic Acids.....	1121
Barrow, J. Recovering Sulphuretted Hydrogen from Gases (P).....	188	Berthelot. Absorption of Carbonic Oxide by the Earth.....	1152
Barrus, G. H. Determining Quantity of Moisture in Steam (P).....	168	Equilibrium and Reciprocal Displacements of the Volatile Alkalis.....	1127
Barth, K. See Hofmann.....	109	Fixation of Atmospheric Nitrogen.....	86
Barthel, A. E. Electro-deposition of Iron (P).....	298	Formation of Ammonia by Plants.....	86
Barton, R. Paints (P).....	954	Oxidation of Sulphur contained in Organic Bodies.....	1069
Bassenge, E. See Egen.....	1116	Reactions between Atmospheric Ammonia and Vegetable Soil.....	525
Bassett, H. A. Manufacture of Building Materials (P).....	1038	Reduction of Alkaline Sulphates.....	1085
Basswitz, C. Treating Textiles by Ammoniac Copper (P).....	1047	Relative Stability of Salts.....	1162
Batchelor, C. L. Preserving Alimentary Substances (P).....	1058	Berthelot and Petit. Different Forms of Graphite.....	595
Batchelor, G. Drying Slurry by Waste Heat (P).....	294	Bertrand-Leplat, J. Dyeing and Treating Textiles (P).....	383
Batchelor, T. C. See Butterfield.....	765, 822	Besnard, J. H. Manufacture of Bread (P).....	882
Bate, J. R., and others. Compounds for Preserving and Embalming (P).....	1059	Bessemmer, H., jun. Obtaining Aluminium (P).....	949
Bates, F. G. Converting Iron into High-grade Steel (P).....	811	Besson, A. Manufacture of Fuel (P).....	273
Baun, H. Aromatic Dithio-oxy-carbon Acids (P).....	98	Bevan, E. J. Discussion on Expulsion of Ammoniacal Compounds from Sulphuric Acid.....	444
Baumann, A. Analysis of Pyrolusite by Hydrogen Peroxide.....	550	See Cross.....	253, 450
Baumann, E., and Kast, A. Physiological Action of Sulphones.....	49	See Green.....	1001
		Beythien, K., Pareus, E., and Tollens, B. Formation of Lactic Acid from Molasses.....	310
		Lactic Acid from Molasses.....	311
		Beythien, K., and Tollens, B. Compounds of Raffinose with Bases.....	309
		Behaviour of Inverted Raffinose with Phenylhydrazine.....	310
		Melting Points of the Ozonozones.....	310
		Properties of Raffinose.....	30

	PAGE		PAGE
Bibikov, N. A. Manufacture of Paints, (P).....	631	Bottinger, C. New Reaction for Tannin .....	555
Biedermann, R. Technisch-Chemisches Jahrbuch, 1888— 1889.....	116	New Reaction for Tannic and Gallic Acids. (Smith).....	450
Biehinger, J. Study of most Volatile Portion of Coal Tar.....	928	On Gallic, Tannic, and Gallotannic Acids.....	955
The Volatile Constituents of Coal Tar.....	728	Boulton, S. B., and others. Apparatus for Mixing Liquids (P).....	44
Biedler, K., and Tollens, B. Fucusaldehyde.....	956	Bourcart, R. Discussion on Diazotype Process.....	1003
Fucusol.....	274	Estimating Alcohol by Chromic Acid.....	557
Biggart, J. W. Discussion on Quantitative Estimation of Colouring Matters.....	41	Bourgoignon, A. Manufacture and Application of Hydrogen Peroxide.....	1062
Biedler, J. See Noppel.....	870	Bowden, J. A. Construction of Filters (P).....	849
Bilharz, O. Treating Crushed Ores (P).....	626	Bowden, J., and others. Washing Composition (P).....	814
Billing, H. E. See Fahrigr.....	101	Bowen, E. Production of Ammoniacal Salts (P).....	1129
Binns, C. F. Producing a Matt Surface on Paper, Photo- graphs, &c. (P).....	1152	Bowers, H. J. A. See Allen.....	727
Birch, P. Discussion on Sewage Purification.....	1095	Box, U. W. Polish for Furniture and Leather (P).....	1047
Bird, R. C. and M. See Page.....	612	Boyd, J. Manufacture of Butter (P).....	405
Birley, H., and Williams, T. Apparatus for Spreading Plastic Materials on Fabrics.....	814	Boyd, R. C. Determination of Manganese and Zinc as Pyro- phosphates.....	973
Bischof, G. Discussion on Sewage Purification.....	1095	Boyd, W. See Campbell.....	508
Bischoff, C. A. Azo Dyes from $\alpha$ -Naphthylamine, Dimethyl- aniline, and a Hydroxynaphthoic Acid.....	932	Boyd, D. See Lamb.....	630
Sulphonation of Aniline and Naphthylamine with Acid Potassium Sulphate.....	932	Boye, H. See Lellmann.....	930, 931
Bischoff, C. A., and Nastvogel, O. Distillation of Rosin in Vacuum.....	927	Boyen, E. von. Refining the Heavier Paraffin Oils of Lignite Tar.....	487
Bishop, A. Burning Lime, and Kilns therefor (P).....	914	Boyer, E. Determination of Mineral Matter in Sugar.....	1161
Bishop, F., and Cowan, A. Coating Photographic Plates (P).....	651	Reduction of Nitric Acid to Ammonia and Estimation of Nitric Acid.....	897
Bishop, M. W. Detection of Sesame Oil.....	112	Bradburn, J. A. See Pennoek.....	861
Black, D. See Robertson.....	1033	Brady, E. L. Anticorrosive Lubricant (P).....	337
Black, W. See Neilson.....	730	Braham, P. Improved Form of Pinch-Cock (illus.).....	253
Black, W., and Rennoldson, W. L. Preparation of Disin- fectants (P).....	644	Braiser, E., and Knowles, J. H. New Dye from "Bauhinia Vahlhi" (P).....	285
Blaikie, W. B., and others. Producing Marble Pattern Papers (P).....	289	Braker, H. See McKenzie.....	762
Blair, J. A. The Organic Analysis of Potable Waters.....	826	Bramley, W. Treatment of Sea Water (P).....	594
Blanc, L. Colouration of Silk by Coloured Food to Silkworms.....	1125	Bramwell, J. H. Hardening Steel (P).....	742
Blandy, A. A. Artificial Leather (P).....	522	Brande, F. See Hilger.....	542
Blass, E. See Fox.....	595	Branson, W. P., and Nield, H. W. Evaporating Milk or other Liquids (P).....	593
Bloehmann, R. Strength of Reagents.....	550	Brausewetter, V. Portland Cement Concrete.....	73
Blondel, R. Otto of Rose.....	1149	Breakell, T., and J. W. Colouring Stones (P).....	1038
Blount, B. Discussion on Expulsion of Ammoniacal Com- pounds from Sulphuric Acid.....	444	Breal, E. Fixation of Nitrogen by Leguminous Plants.....	305
Discussion on Tempering Steel.....	145	Breadard and Cathelneau. Iodine Cotton-Wool.....	412
Bluemel, E. A. Coating Articles with Xylonite or Celluloid (P).....	522	Brémond, L. Wery's Apparatus for Heating Retort Furnaces.....	168
Blum, L. An Impurity in Barium Chloride.....	766	Brønner, A. A. Fixation of Atmospheric Nitrogen.....	61
Detecting Natural Mineral Phosphates in Thomas' Phos- phate Meal.....	970	Sterilisation of River Water by Mine Water.....	1058
Estimation of Sulphur in Iron.....	769	Brevoort, H. L. See Roberts.....	868
Volumetric Estimation of Zinc.....	969	Brewster, J. B. Amalgamator for Extracting Metals (P).....	296
Bluman, F., and Sims, F. M. Apparatus for Burning Heavy Hydrocarbon Oils (P).....	274	Breyer, F. Asbestos Filters (P).....	796
Bonke, A., and Roberts, F. G. A. Applying Antiseptic Agents to Beer and Wine (P).....	1057	Briggs, E. H. Apparatus for Manufacture of Water-Gas (P).....	274
Böckmann, O. See Friedländer.....	50	Brinck, G. A., and Rehnström, A. W. Food Preparations (P).....	818
Bode, F. Improvement of Sulphuric Acid Process.....	181	Brinck, W. Lubricants (P).....	952
Bodlander, G. A Double Salt of Dithionie Acid.....	1127	Brin, L. Q. and A. Extracting and Refining Iron (P).....	193
Boettinger, C. Oxidation of Gallic Acid, Tannin, and Quer- citanic Acid.....	746	Production of Aluminium Electrically (P).....	81
Bogenschild, H., and Busch, E. Glazing Leather (P).....	1048	Brin's Oxygen Co., Lim. See Thorne.....	1046
Bohm, Estimation of Cane Sugar.....	114	Brockhock, T. de. Manufacture of Anhydrous Barium Oxides (P).....	510
Estimation of Cane Sugar by Inversion.....	114	Brocklehurst, C. G. B. Preparing Zinc Plates for Lithographic Purposes (P).....	630
Bojret, Destruction of Clover Silk by Iron Sulphate.....	746	Bronfield, J. C. Manufacture of Iron and Steel (P).....	810
Bolas, T. Discussion on Diazotype Process.....	1004	See Sahlström.....	1115
Bon, L. Apparatus for Drying Sugar Cane Trash (P).....	1054	Bronner, P. Manufacture of White Lead (P).....	630
Bondzynski, S., and Ruff, H. Butter Fat.....	421	Brook, E. and J. J. Regenerative Kilns (P).....	170
Bonnami, H. Testing Materials in Tension and Compression.....	215	Brough, B. H. Outbursts of Gas in Metalliferous Mines.....	191
Bonne, C. R. Manufacture of German Yeast (P).....	403	Brown. Discussion on Mechanical Retort.....	1022
Bonnier, G. Experimental Cultures at High Altitudes.....	525	Brown, A. J. Numerical Increase of Yeast Cells.....	531
Bonte, R. Permeability of Tiles.....	73	Brown, A. K. Apparatus for Softening Water (P).....	406
Bony, P. See Million.....	813	Brown, C. A. Machinery for Dressing Hides (P).....	815
Bookwalter, J. W. Converters (P).....	950	Brown, E. H. See Hussey.....	812
Booth, W. S. A New Vegetable Fibre (P).....	1034	Brown, H. T., and Morris, G. H. Estimation of Amyloins, and Analysis of a Beer of the Last Century.....	535
Booty, A. Manual Composition (P).....	525	Germination of Some of the Gramineæ.....	530
Borchers, W. Unhairing Skins (P).....	870	Brown, H. T., and others. Manufacture of Beer (P).....	1057
Bordman, J. J. Pulverising Machines (P).....	796	Brown, J. D. Manufacture and Treatment of Iron and Steel (P).....	951
Bordt, F. See Bamberger.....	493	Brown, J., and Johnston, G. Vacuum Drying Apparatus (P).....	594
Borland, W. D. Machine for making Cartridges (P).....	215	Brown, R., and Irvine, G. H. Wet Method of Extracting Gold (P).....	810
Bormann, C. The Götz Method of Determining Phosphorus.....	111	Brown, T. Measure and Funnel for Liquids (P).....	43
Bornträger, A. Estimation of Sugar and Polarimetric Obser- vations in Sweet Wines.....	115	Brownen, G., and Gamgee, J. Apparatus for Bleaching and Disinfecting (P).....	883
Bornträger, H. Substances Occurring in Raw Spirit.....	402	Brownsword, F., and Cohen, J. B. Product of Distillation of Rosin.....	16
Borucki, L. Drying Oils.....	418	Bruce, J. Manufacture of Yeast (P).....	538
Bosset, A. Manufacture of Linseed Mucos (P).....	809	Bruce, R., and others. Filters (P) (illus.).....	725
Bothamley, C. H. Orthochromatic Photography.....	103	Bruce, W. K. Vacuum Pans (P).....	922
Standard Method of Development.....	891	Bruck, G. J. See Trobach.....	1034
Böttcher, O. Adulteration of Chili Saltpetre.....	67	Bruckner, C. Condensation of Dichlorether with the Cresols.....	929
Bottinger, C. Action of Phenylhydrazine on Tannin Extracts.....	955	Bruch, L. Drywoods and Extracts, their Use and Abuse.....	605
Action of Reducing Agents on Gallic Acid and Tannins.....	902	Brugelmann, G. Characteristics of Alkaline Earths and of Zinc Oxide.....	706
Benzoyl tannin.....	84		

	PAGE
Bühl, J. W. Apparatus for Decomposing under Diminished Pressure (illus.).....	967
Concentration of Solar Rays.....	895
Brull, The "Godillot" Furnace for Inferior Fuels (illus.)....	44
Brüngger, H. See Salomon.....	321
Brünner, A. Farinaeous Food for Animals (P).....	92
Brunner, H. Valuation of Roofing Slates.....	393
Brunner, P. See Clayton Aniline Co.....	854
Bryan, S. G. T. C. Making Building Blocks from Slag (P)....	1088
Buchanan. Discussion on Gold Extraction.....	270
Buchner, O. See Hilker.....	521
Buecher, A. Solutions for Removing Rust Stains from Cloth (P).....	612
Bull, H. See Dreyfus.....	285
Bull, J. C. Manufacture of Copper Alloys (P).....	741
Manufacture of Metallic Alloys and Compounds (P).....	1134
Burardorf, C. See Bamberger.....	605
Burgemeister, A. Life of Sulphuric Acid Chambers.....	67
Burgers, P. Use of Carbon and Coke Bricks in Blast Furnace Hearths.....	625
Burghardt, C. A. Application of Caustic Soda or Potash and Carbon to Analysis of Minerals.....	417
Manufacture of Nitrate of Ammonium (P).....	623
Burn, R. S. Treating Cotton Fibres (P).....	855
Burnley, W. Galvanic Batteries (P).....	521
Burrell. See Fairley.....	1161
Burton, Gelatino-Bromide Emulsions.....	892
Barrows, T. Treating and Ungumming Fibres (P).....	1033

Evaporating Apparatus (P).....	1115
Wrigley, E. G. Manufacturing Absorbent Sheets of Paper (P).....	1145
Wander, J. Preparation of Ultramarine.....	1137
Wyeth, W. E. See Button.....	812
Wynne, W. P. See Armstrong.....	282, 799, 802, 803
Wyss, G. Report on Sorel's Paper on Fabrication de l'Acide Sulfurique.....	175

## Y

Yates, J., and Kay, G. Dyeing and Soaping Fabrics (P)....	289
Yeadon, J. A., and Adie, W. Retorts for Distillation of Coal (P).....	797
Young, W. Evaporating Brine under Vacuum (P) (illus.)....	860
See The Coltness Iron Company.....	1120
Young, W., and Beilby, G. T. Distillation of Mineral Oils (P) (illus.).....	278
Younger, W. Analysis of Deacon Gases (illus.).....	159
Estimation of Arsenic Acid.....	158

## Z

Zaboziecki, R. Determination of Ferrocyanides in Gas Residues.....	767
Estimating Ferrocyanide in Yellow Prussiate Melt.....	767
$\alpha$ -Naphthol-Benzene, a New Indicator.....	770
Zarling, R. Derivatives of Nitro- $\beta$ -Naphthaquinone.....	492
Zaunscharf, H. Analysis of Celluloid.....	979
Zdrhal, A. Imperial Silver and Lead Works at Příbram.....	946
Zeisel, S. See Herzog.....	900
Zen, P. See Leonardi.....	84
Ziegler, A. Analysis of Tungsten, Ferro-Tungsten, Tungsten Steel, Ferro-Chromium and Chromium Steel.....	216
Ziegler, T. H. Influence of Sulphur on Organic Compounds and Synthesis of Tetraphenylthiophen.....	1026
Production of Aromatic Sulphides and Thioxanthone....	1026
Zimmer, G. C. Manufacture of Colouring Matters (P).....	385
Zincke, T. Azo Derivatives of Phenyl- $\beta$ -Naphthylamine.....	929
Zincke, Th., and Küster, F. Action of Chlorine on Pyrocatechol and $\alpha$ -Aminophenol.....	601
Zingler, M. Treating Fibres and Textiles (P).....	321
Zulkowski, K., and Peters, K. Orcin.....	1123
Zwicker, F. See Korenar.....	522

## INDEX OF SUBJECTS.

N.B.—In this Index (P) indicates that the matter referred to is an abstract of a patent; (T.R.) indicates that the matter referred to is in the Trade Report.

	PAGE
<b>A</b>	
Aachen, Chemical Society of.....	972
Abrin.....	544
Accounts for the Year 1889.....	690
Acetanilide, Examination of. (Ritsert).....	1068
Acetanilidine, p.....	650
Acetates, Manufacture of Soluble. (P) Johnson-Johnson.....	293
Acetic Acid, Imports of, by New South Wales. (T.R.).....	335
Italian Customs Report on.....	1036
Manufacture of. (P) Farmer.....	859
Manufacture of. (P) Johnson-Johnson.....	293
Rate of Distillation of. (Wilson).....	18
Acetone, Estimation of, by Iodoform. (Arachequesne).....	660
Estimation of, in Crude Wood Spirit. (Vineat and Delachanal).....	824
Estimation of, in Wood Spirit. (Vignon).....	659
Investigations of Crude. (Wolfes).....	1147
Manufacture of. (P) Ferichs.....	1130
Acetyl Numbers of Fats, The. (Wachtel).....	979
Acetylene, Condensation of. (Schutzenberger).....	852
Acetylenedicarboxylic Acid, Aconitic Acid from. (Lövén).....	323
Acetyl Values, On Benedikt's. (Lewkowitsch).....	660
Acetylresorufinol. (Nietzki and others).....	490
Acid Fixing Bath. (Beach).....	892
(A. Lainer).....	102
Acid Green. (P. Friedlander).....	50
Acid Liquors, Treatment of. <i>See</i> Residues.	
Acid Towers, Distribution of Liquid in. (Lunge) (illus.).....	66
Acid Violet X, and Patent Blue. (Ulrich).....	384
Acidity of Malt Liquors. (Jones).....	313
Acids, Action of Mineral, on Saccharification and Fermentation. (Effront).....	748
Crystallisation of. (P) Garton and Lawrence.....	727
Of Low Carbon Density in Baku Petroleum. (Aschan).....	597
Of the Sugar Group, Reduction of. (Fischer).....	638
Preparation of New Sulphonic. (P) The Clayton Aniline Co. and Dreyfus.....	853
Preventing Formation of, in Malting Barley. (P) Paterson.....	961
Synthesis of Alcohol, of the Pyridine Series. (Einhorn).....	644
Volatile Fatty, from Dextrose. (Loew).....	637
Aconitic Acid, Synthesis of. (Lövén).....	323
Aconitine. (Merek's Bull.).....	322
Actinograph, The. (Hurter) (illus.).....	370
Actinometer, A New. (Ballard) (illus.).....	469
(Hurter) (illus.).....	370
Address at Ninth Annual Meeting, President's.....	491
Adhesive Solution. (P) Saunders and others.....	398
Aerated Fuel Company's System for Burning Oil (illus.).....	48
Aerated Waters. <i>See</i> Waters.	
Africa, Export Duties of West Coast of. (T.R.).....	120
Minerals in South. (T.R.).....	428
Production of Indigo in Western. (T.R.).....	222
Agricultural Chemistry, Lecture Experiments in. (Müller).....	106
Agricultural Experiments in Kentucky.....	399, 874, 1048
Of Sir J. B. Lawes.....	871
Air, Action of, on Cement. (Toméi).....	73
And Gas Comminglers. (P) Popplewell, From Mitchell.....	925
Apparatus for Manufacture of Gas from. (P) Fritz.....	925
Contained in the Soil. (Schloessing).....	305
Manufacture of Gas from. (P) Monier.....	924
Saturating with Hydrocarbon Vapor. (P) Scott.....	925
Use of, in Malting. (Stopes).....	314
Air Bath, A Constant. (Grimshaw) (illus.).....	471
Alang-Alang, Production of. (T.R.).....	223
Albuminoids, New Reactions of. (Reichl).....	960
Alcohol, Compound of Normal Propyl and Calcium Chloride. (Gottig).....	541
Denaturing by Wood Spirit and Pyridine. (Hofmann and Krauer).....	323
Detection of Impurities in. (Möhler).....	1155

	PAGE
Alcohol, Industrial Use of, in United States. (T.R.).....	225
New Means of Estimating. (Bourcart).....	557
Process and Apparatus for Rectifying. (P) Barlet.....	318
Production of. (P) Thompson, From Marix and Notkin.....	852
Purification of. (P) Luck.....	538
Purification of. (Waller).....	329
Purifying. (P) Rousseau and others.....	757
Quality of Commercial. (Szilagy).....	402
Transformation of, into Aldehyde. (Linossier and Roux).....	879
Treatment of Commercial. (P) Sorel.....	203
Treating by Electricity. (P) de Méritens.....	758
Alcohol Acids of the Pyridine Series, Synthesis of. (Einhorn).....	644
Alcoholic Beverages. (P) Malzy.....	204
Alcoholic Extract of Brewers' Yeast. (de Rev-Pailhade).....	756
Alcoholic Liquors, Destroying Microbes in. (P) Spilker and others.....	319
Rectifying by Electricity. (P) Méritens.....	205
Sterilising Fermented. (P) Euzinger.....	403
Alcohols, Distillation and Rectification of. (P) Whiteman, From Haack.....	881
Presence of Furfuraldehyde in Commercial. (Lindet).....	1135
Secondary Ring. (Bamberger and Lötter).....	493
Treatment of Commercial. (P) Sorel.....	204
Aldehyde, Transformation of Alcohol into. (Linossier and Roux).....	879
Aldehydes. (Bielringer).....	729
Alfa, Production of, in Algeria. (T.R.).....	426, 906
Allylic-β-tetrahydronaphthol and Secondary Ring Alcohols (Bamberger and Lötter).....	493
Alizarin Green, S.W. (Knecht).....	54
Indigo Blue. (Knecht).....	54
Rendering Dry, fit for Colouring Purposes. (P) Romen.....	1034
Yellow. (Knecht).....	54
Alkali Co., Lim., The United. Construction and Objects of. (T.R.).....	1078
Alkali Industry, Present Condition of. (T.R.).....	672
Alkali Metals, Compounds of, with Ammonia. (Bakhuis-Roozeboom) (P) Joannis.....	507
Alkali Union, The Proposed. (T.R.).....	568
Alkali Waste and Black Ash, Treatment of. (P) Hargreaves and Robinson.....	780
Estimation of Available Soda in. (Lunge).....	509
Alkali Works, New Analytical Methods for. (Lunge).....	1013
Report of Chief Inspector of, for 1889.....	618
Alkaline Earths and Zinc Oxide, Characteristics of. (Brügelmann).....	766
Alkaline Sulphides, Formation of. (T.R.).....	674
Alkalis, Determining, in Presence of Sulphites. (Grant and Cohen).....	19
Equilibrium and Reciprocal Displacements of the Volatile. (Berthelot).....	1127
Presence of Boracic Acid in Caustic. (Venable and Callison).....	968
Alkaloids, Borates of.....	543
Determinations of, and their Molecular Weights. (Christensen).....	1160
Functions of, in Seeds. (Heckel).....	324
Italian Customs Report on. (T.R.).....	1079
Mydriatic, of the Solanacee. (Merek's Bull.).....	322
Notes on the. (Dott).....	42
Of Atropa Belladonna. (Schmidt).....	1147
Of Cod Liver Oil. (Gautier and Mourgues).....	647
Of the Areca Nut. (Jahns).....	1146
Reactions of Salts of the. (Colson).....	1155
Alloy, A New. (P) Clark, From Soc. en Part. Bourbouze et Cie.....	519
For Resisting Acids. (Rieth).....	296
Alloys, Apparatus for Coating Metals with. (P) Taylor.....	740
Certain Ternary. (Wright and Thompson).....	944
Coating Metal Effects with. (P) Heathfield.....	396
For Anti-friction. (P) Müller, From Mongolia Anti-friction Metal Co.....	867
Manufacture of Copper. (P) Bull.....	741
Manufacture of Metallic. (Dick).....	395
Metallic. (P) P. M. Parsons.....	77

	PAGE		PAGE
Alloys, Removing Gases and Impurities from. (P) Sebenius .	741	Ammonia, Formation of, from Free Nitrogen. (Loew).....	979
Use of, in Metal Work. (Roberts-Austen) .....	740	Manufacture of. (P) Feldmann .....	230
Alloys and Compounds, Manufacture of Metallic. (P) Bull.....	1134	Manufacture of Sulphate of. (P) Ellis (illus.).....	734
Alsopp and Sons, Visit to Messrs. ....	715	Manufacture of Sulphate of. (P) Wilton .....	623
Altitudes, Experimental Cultures at High. (Bonnier).....	525	Nitrification of. (Schlosing) .....	86
Alm, Manufacture of. (P) Spence .....	1129	Obtaining. (P) Fell. From the American Ammonia Manu- facturing Company .....	392
Manufacture of Soda-. (P) Augé .....	510	Obtaining from Ammonium Chloride. (P) Bale .....	861
Alumina, Determination of. (Kretschmar) .....	1064	Obtaining from Ammonium Chloride. (P) Mond (illus.) ..	291
Determination of, in Crude Phosphates. (Stutzer) ..	218	Precipitation of Aluminium and Iron by. (Lunge) ..	111
Electrolysis of. (Minet) .....	520	Production of Cupr-. (P) Hine and Nead .....	391
Estimation of, by Titration. (Cruss and Bevan) ..	253	Production of Sulphate of, 1870-89 .....	633
Volumetric Determination of, in Aluminates. (Lunge) ..	767	Reactions between, and Vegetable Soil. (Berthelot) ..	525
Aluminium, Aceto-tartrate .....	498	Recovery of, from Fuel. (P) Wilkinson .....	734
Action of Nitric Acid on. (Ditté) .....	654	Recovery of, in Galvanising. (P) Saunders .....	195
Action of Sulphuric Acid on. (Ditté) .....	549	Reduction of Nitric Acid to. (Boyer) .....	837
Alloys of, with Steel and Iron. (P) Pearson and Pratt ..	1041	Role of, in Nutrition of Plant Life. (Muntz) ..	200
And Alloys. (P) Petit-Devanille .....	195	Saturators for Sulphate of Plant. (P) Kennedy ..	511
And Iron, Determination of, in Phosphates. (E. Glaser) ..	111	Separation of, from Gases. (P) Muckay .....	1120
And Iron, Precipitation of, by Ammonia. (G. Lunge) ..	111	Statistics of Sulphate of. (T.R.) .....	130
Bronzes, Tests of. (Dazzer) .....	1131	Ammonia-Soda, Obtaining Chlorine from Residual Liquors of. (P) Lyte and Tatters .....	1128
Decoration of Glass and Porcelain by. (Gehring) ..	943	Obtaining Hydrochloric Acid from Residue of. (P) Lyte and Tatters .....	1129
Distribution of, in Plants. (Ricciardi) .....	525	Processes. (H. Schreib) (illus.) .....	61
Effect of, on Manganese Steel and Spiegel Eisen. (Dazzer)	1133	Ammonium Base from <i>p</i> -Toluene-azo- $\beta$ -naphthylphenylamine Ammonium Chloride, Apparatus for Volatilising. (P) Mond (illus.) .....	929
Estimation of Metallic in Commercial. (Klemp) ..	969	Manufacture of. (Dubosc and Heuzey) ..	291
Extracting, from Cryolite. (P) Netto .....	195	Obtaining Ammonia, Chlorine, and Hydrochloric Acid from. (P) Bale .....	614
Extraction and Electro-Deposition of. (P) Marino ..	297	Volatilising. (P) Mond (illus.) .....	291
Fluoride, Dissociation of. (Asboth) .....	945	Ammonium Formate, Action of, on Ketones. (Leuckart) ..	649
Fluoride, Electrolysis of. (Minet) .....	520	Ammonium Iodide. (Weissenberger) .....	891
Hydroxide, Relations of, to Ferric Salt Solutions. (Schnei- der) .....	857	Ammonium Nitrate, Manufacture of. (P) Burghardt ..	623
In Carburetted Iron. (Keep) .....	864	Manufacture of. (P) Carez .....	292
In Iron. (Howe) .....	946	Producing. (P) Wahlenberg .....	293
In Iron and Steel, Discussion on Determination of ..	20	Ammonium Sulphate, Manuring with, and with Chili Salt- petre. (Maercker) .....	306
Manufacture of. (P) Daniel .....	520	Ammonium and Cesium Bromide .....	889
Manufacture of, and its Alloys. (P) Diehl .....	297	Ammoniacal Compounds, Expulsion of, from Sulphuric Acid. (Moritz) .....	443
Manufacturing. (P) Dixon .....	1042	Liquids, Distillation and Condensation of. (P) Solvay and Co. (illus.) .....	622
Obtaining. (P) Bamberg .....	741	Salts, Production of. (P) Bowen .....	1129
Obtaining Alloys of. (P) Bamberg .....	741	Amphigene, Formation of. (Friedel) .....	807
Obtaining Alloys of. (P) Green .....	741	Amylaceous Matter, Fermentation of. (P) Thompson. From Soc. Gen. de Maltose .....	313
Producing Electrically. (P) L. Q. Brin and A. Brin ..	81	Amylamine .....	648
Production of. (P) Bessemer .....	949	Amylene Hydrate .....	650, 889
Production of. (P) Green .....	298	Amyl Nitrite, Tertiary .....	213
Properties of. (Hunt, Langley, and Hall) .....	738	Amyloins, Estimation of. (Brown and Morris) ..	533
Pure Double Chlorides of. (P) Castner .....	297	Andanson Paper. (Herzberg) (illus.) ..	758
Purifying Chloride Compounds of. (P) Castner ..	1136	Aniline, Action of Light in Colouring Pure. (Veruer) ..	278
Salts, Direct Determination of Total Acidity in. (Heiden- bain) .....	1154	Action of, on Bleached Cotton. (Lipkowski) ..	1125
Steel. (Hadfield) .....	1131	Chlorination and Bromination of. (Hafner) ..	52
Sulphate, Determination of Free Sulphuric Acid in. (Belstein and Grosset) .....	416	Sulphonation of, with Acid Potassium Sulphate. (Bischoff)	932
Sulphate, Hydrated Neutral. (Delcharlenwz) ..	1127	Aniline Black, Steam. (Kertész) .....	387
Amalgamation of Gold Ores. (Richards) .....	656	Method of Dyeing. (P) Schreiner .....	939
Amalgamator for Separation of Gold and Silver from Ores. (P) Pfeiffer .....	810	Notes on Dyeing. (Persoz) .....	500
Amalgamators for Extracting Metals. (P) Thompson. From Brewster .....	296	Aniline Dyes in Japan. (T.R.) .....	335
Amalgams, Index to Literature on. (Dudley) .....	513	Use of, in China. (T.R.) .....	775
The Nature of. (Dudley) .....	512	Animal and Ivory Black, Italian Customs Report on. (T.R.) ..	1079
Ambergris, Effect of Excessive Price of. (T.R.) .....	429	Animal Oil, Classification of, in Swiss Customs Tariff .....	220
American Imports at Barranquilla. (T.R.) .....	668	Animals, Action of Related Chemical Compounds on. (Gibbs and Hare) .....	324
America, Sulphite Pulp in. (Chem. Trade J.) ..	540	Experimental Feeding of. (Lawes) .....	873
Amethylamphosphonulphone. (Cazeneuve) ..	853	Annealing of Metals. (Faurie) .....	625
Amido-azo Compounds. (Goldschmidt and Rosell) ..	494	The Laws of. (Le Chatelier) .....	625
Amidoazonaphthalene, Reduction of. (Friedlander) ..	50	Annual Dinner .....	178
Amidobenzylsulpho Acid, Colouring Matters from. (P) Bang. From Dahl and Co. ....	853	Meeting, Proceedings at the Ninth .....	689
Amidochrysene. (Abetz) .....	600	Anodines or Obtundents, Dental. (P) Hunter .....	102
(Bamberger and Burgdorf) .....	605	Anorthite, Formation of. (Friedel) .....	807
Amido-dioxy-naphthalin Monosulphonic Acid. (P) Imray. From The Farb. vorm. Meister, Lucius, and Brünig ..	854	Anthracene Yellow. (Farb. F. Bayer and Co.) ..	937
Amido-naphthol-mono-sulphonic Acids. (P) Imray. From The Farb. vorm. Meister, Lucius, and Brünig ..	855	Anthracene and Anthraquinone, Homologues of. (Ellis). ..	276, 598
Amidonaphtholsulphonic Acid, Preparation of. (P) Pitt. From Casella and Co. ....	935	Anthraquinone, Formation of, under Peculiar Conditions. (Friedberg) .....	1031
Amidonaphthophenazine. (Zartling) .....	493	And Anthracene. (Ellis) .....	598
Amido-oxy-naphthalin Disulphonic Acid. (P) Imray. From The Farb. vorm. Meister, Lucius, and Brünig ..	854	And Anthracene, Homologues of. (Ellis) ..	276
Amidophenol, Action of Chlorine on $\alpha$ -. (Zincke and Kuster)	601	Antimony and Arsenic, Quantitative Separation of. (Koehler)	768
Amidophenols, Ethylene Ethers of. (Krohn) .....	280	Electrolytic Estimation of. (Leclercq) .....	108
Manufacture of. (P) Lake. From Leonhardt and Co. ....	608	Mines, French .....	1039
Amido-quinones and Quinone-imides. (Kehrmann) ..	603	Ore, Tenders for Purchase of, from Serbian Government. (T.R.) .....	1164
Amines, Action of Sulphur on certain Primary Aromatic. (Anschutz und Schultz) ..	49	Ores in Spain. (T.R.) .....	428
Ammonia, Absorption of, from Air by Soil. (Schloesing) ..	635	Ores, Treatment of. (P) Schreiber and Knutsen ..	195
Amount of Sulphate of, produced in the United Kingdom And Resorcinol, Metaphenylene-diamine from. (Seyewitz)	620	Production of, in Turkey. (T.R.) ..	120
Catalytic Formation of, from Nitrates. (Loew) ..	634	Quantitative Determination of, by Marsh's Method. (Bylert) .....	1153
Compounds of Mercury Chloride with. (André) ..	647	Separating Gold from. (P) Sanderson .....	952
Compounds of the Alkali Metals with. (Bakhuys-Roodeboom)	507	Anti-corrosive Composition for Metals. (P) Thompson. From Leonardi and Zen .....	84
Compounds of the Alkali Metals with. (Joannis) ..	508	Compound. (P) Fulton. From Schmid .....	814
Direct Assimilation of, by Plants. (Muntz) ..	524		
Estimating in Filter Sand and Sewage. (Hazen) ..	1070		
Formation of, by Plants. (Berthelot) ..	86		

	PAGE
Antifebrin, Ezalgin, and Phenacetin, Distinction of. (Hirschsohn).....	329
Anti-ferustators, Tannin Matters as. (Vignon).....	767
Antipyretic, a New. (Kobert).....	412
Antipyrine and Carboic Acid, Incompatibility of.....	650
And Nitrites, Antagonism of.....	213
Antiseptic Compounds. (P) Ascouh.....	68
For Use in Saccharification or Fermentation. (P) Thompson From La Soc. Gen. de Maltosa.....	960
Manufacture of a New. (P) Johnson. From Salomon.....	1059
Antisepsies. (P) Roberts and others.....	98
(P) Tweedie.....	98
Apparatus for Periodic Dispersion of. (P) Upward.....	406
Applying to Wine, Beer, &c. (P) Boake and Roberts.....	1057
Apioi. (Ginsberg).....	615
And its Derivatives, Constitution of. (Ciamichan and Silber).....	962
Appliances, Exhibition of Chemical, in Berlin. (T.R.).....	597
Apo-atropine.....	889
Apocynaceæ, The. (Chem. and Drug.).....	1151
Arabinon. (O'Sullivan).....	400
Arecaidine. (Jahns).....	1146
Areca Nut, Alkaloids of the. (Jahns).....	1146
Arctic, Preparation and Properties of. (Moissan and Landrin).....	616, 1061
Arecoline. (Jahns).....	761
Argentine Republic, Customs Law for 1890. (T.R.).....	221
Tariff Changes in. (T.R.).....	1164
Aromatic Compounds, Chlorinating. (Pétricon).....	731
Arsenic and Antimony, Quantitative Separation of. (Koehler).....	768
And Cadmium, Electrolytic Separation of. (Smith and Frankel).....	1067
And Copper, Separating by Electrolysis. (McGey).....	822
And Copper, Electrolytic Separation of. (Smith and Frankel).....	1067
And Mercury, Electrolytic Separation of. (Smith and Frankel).....	1067
And Silver, Electrolytic Separation of. (Smith and Frankel).....	1067
Occurrence of, in Zinc Oxide. (Strömeyer).....	766
Quantitative Determination of, by Marsh's Method. (Kuhn and Sæger).....	1152
Arsenic Acid, Estimation of. (Yoncker).....	158
Artificial Silk Composition. (P) du Vivier.....	286
Asbestos Filters. (P) Broyer.....	796
Aselline. (Gautier and Morgues).....	648
Asphalt and Petroleum in Mexico. (T.R.).....	427
Artificial. (P) Erslev.....	71
Paving. (Dehnhardt).....	73
Asphaltum, Exports of, from Trinidad. (T.R.).....	561, 669
Ash Determination in Raw Sugars. (Weichmann).....	330
From Paper Mills, Treatment of. (P) Kynaston and Sutherland.....	408
Assam, Petroleum Deposits of. (Redwood) (illus.).....	359
Atmosphere, Drying Substances in a Rarefied. (Sidersky) (illus.).....	967
Atropa Belladonna, the Alkaloids of. (Schmidt).....	1147
Atropine. (Weller).....	761
Relation of, to Cocaine. (Einhorn).....	890
Auckland, Opening of Sulphuric Acid Works near. (T.R.).....	339
Auroline.....	285
Australasia, Customs Tariffs of. (T.R.).....	1075
Australia, Exports of Sandalwood from Western. (T.R.).....	776
Austria, Discovery of Quicksilver in. (T.R.).....	907, 1040
Customs Regulations concerning Creoline. (T.R.).....	424
Azines, Formation of, from Orthodiamines and Polyamines. (Nietzki).....	490
Azo-Carmine. (Knecht).....	53
Azo-Derivatives of Phenyl- $\beta$ -Naphthylamine. (Zincke).....	929
Azo Dyes and Colours. See Colouring Matters.	
Azotometer for Estimating Nitrogen in Ammonium Salts. (Hentschel).....	971
Azoxyaniline, and Colouring Matters therefrom. (P) Inray. From Soc. Anon. des Matières Colorantes.....	1124

## B

	PAGE
Baku, Benzol Manufacture in. (T.R.).....	780
Distilleries, Production of, in 1889. (T.R.).....	563
Notes from. (T.R.).....	1079, 1165
Petroleum Trade of. (T.R.).....	777
Reports from. (T.R.).....	427
Balance, Gas. (Lux) (illus.).....	115
Balances, Hydrostatic. (P) Favier.....	408
Balata and India-rubber Produce of British Guiana. (T.R.).....	775
Balsams and Resins, Analysis of. (Bamberger).....	659
Banana Paper. (T.R.).....	820
Barcelona, Exhibition at. (T.R.).....	671
Barium Carbonate, Impurity in Commercial. (Weyscheider).....	415
Chloride, An Impurity in. (Blum).....	766
Oxides, Manufacture of Anhydrous. (P) Leigh. From de Brochocki.....	510
Barley and Grass, Manurial Experiments on. (Kinch).....	308
And Malt, Vacuum Method of Drying. (Rieber).....	756
Influence of Germination on the Constituents of. (O'Sullivan).....	535
Mealy and Glassy. (Just and Heine).....	91
Nitrogen, Free Extract of. (Lintner).....	1053
Preventing Formation of Acids during Malting of. (P) Paterson.....	461
Production of Cider from. (Jacquemin).....	1054
Barranquilla, American Imports at. (T.R.).....	668
Barrels, Lining, to Resist Acids. (P) Bell.....	519
Baryta-raffinate. (Beythien and Tollens).....	810
Barytes Mines, Cleator Iron Co's. (Addison).....	953
Basic Furnaces, Obtaining Uniform Products from. (P) Pszczolka.....	810
Process, Progress of, in 1889. (T.R.).....	225
Bass Fibre, New, of Lagos.....	1032
Bass, Ratchiffe, and Grettton, Lim., Visit to Messrs.....	715
Batteries, Various:—	
Accumulators, Electrical. (P) Fuller.....	80
Construction of Electric. (P) Weyde and others.....	568
Charging Plates for Electrical. (P) Currie.....	81
Electric (Dry). (P) Bonine. From Meinecke.....	712
Electric. (P) Lake. From The Crosby Electric Co.....	812
Electric. (P) Lake. From Hussey and Brown.....	812
Electric. (P) Lake. From Lacombe and Co.....	298
Electric. (P) Johnson. From Gendron.....	81
Electric. (P) Vavasour.....	1041
Electric (Two-Fluid). (P) Weymersch and McKenzie.....	869
Electrical. (P) Thompson. From Parrish.....	299
Electro-Chemical. (P) Brougham. From Lloyd and Fils.....	196
Galvanic. (P) Allison.....	1106
Galvanic, and Accumulators. (P) Crompton and Fitzgerald.....	952
Galvanic. (P) Burnell. From Wilms.....	742
Galvanic (Portable). (P) Davis.....	628
Galvanic. (P) Hitecock. From Burnley.....	521
Galvanic. (P) Irish.....	197
Galvanic. (P) Million and Bony.....	813
Galvanic. (P) Roberts and Brevoort.....	868
Galvanic. (P) Schanschiff.....	868
Gas. (Mond).....	42

Diamines, Action of Quinones on o-. (Leicester).....	1029
Diamond Black. (Chem. Zeit.).....	1126
(Farb. F. Bayer and Co.).....	937
Diastase, Action of, on Ungelatinised Starch. (Littner).....	402
A Mixture of Maltase and Dextrinase. (Wijsman).....	752
Studies on. (Littner and Eckardt).....	91, 318
Diazo and Phenolic Group, Molecular Interchange between. (Lellmann and Boye).....	931
Diazobenzene, Combination of, with $\alpha$ - $\beta$ -Dinaphthylamine. (Matthes).....	281
Diazo-Compounds, Decomposition of Aromatic. (Friedlander).....	50
Compounds of Amido-naphthol-mono-sulphonic Acids. (P) Imray. From The Farb. vorm. Meister, Lucius, and Brünig.....	855

Diazo-Compounds of Amido-oxy-naphthalin Mono- and Di-sulphonic Acids. (P) Imray. From The Farb. vorm. Meister, Lucius, and Brünig.....	854
Compounds, Researches on. (Gattermann).....	823
Sulphonic Acids, Application of Sandmeyer's Reaction to. (Tobias).....	824
Sulphonic Acids, Decomposition of. (Tobias).....	824
Diazotype Photographic Dyeing and Printing. (Green, Cross, and Bevan).....	1001
Dichlorether, Condensation of, with the Cresols. (Bruckner).....	920
Dichloronaphthalenes, Derivatives of 1:3. (Clève).....	604
Digesters for Paper Pulp. (P) Keys.....	541
Digitalin and Tanizinin. (Arnaud).....	324
Researches on Crystallised. (Arnaud).....	323
Digitalins, Comparative Activity of Different. (Bardet).....	324
Digitonin, Composition of. (Kiliani).....	820
Dihydrolutidine. (Gautier and Mourgues).....	648
Dihydroxydiphenylamine, Synthesis of. (Seyewitz).....	280
Dihydroxynaphthalene, On 2,7. (Clausius).....	495
Dihydroxyphenazine Hydrochloride. (Fischer and Hepp).....	602
Di-iodosalicylic Acid.....	544
Dilution Tables for Practical Use. (Herz).....	412
Dimethylaniline, Azo Dyes from. (Bischhoff).....	932
Dinaphthylamine- $\alpha$ - $\beta$ , Combination of, with Diazobenzene. (Matthes).....	281
Dinitrodichloronaphthalene I. (Clève).....	604
Dinitrosoresorcinol, Use of. (Ulrich).....	1127
Dinitrotriphenylamine.....	1028
Dinner, The Annual.....	718
Dinsmore Process, The Chemistry of the. (Smith) (illus.).....	444
Dioxynaphthalenemonosulphonates, Azo-Colouring Matters from. (P) Imray. From The Farb. vorm. Meister, Lucius, and Brünig.....	803
Diphenylamine Blue, Composition of. (Hansdörfer).....	933
Diphenylamine Derivatives. (Nietzki and Ernst).....	932
Diphenyl Bases. (Noelting and Werner).....	1122
Derivatives, New. (Tauber).....	600
Diphenylhydrazine, Derivatives of. (Stahl).....	902
Diphenylmethane Group, Producing Compounds of the. (P) Imray. From The Farb. vorm. Meister, Lucius, and Brünig.....	1124
Diphenyl-naphthylamine.....	1028
Diphenylthiocarbazinic Acid.....	903
Diplomatic Reports.....	118, 334, 426, 560, 664, 774, 827, 905, 984, 1164
Diresorcinol, Detection of, in Synthetical Phloroglucinol. (Herzig and Zeisel).....	900
Diresorcinoltetrazolbenzoate. (Skraup).....	410
Disazo Colouring Matters. (P) Johnson. From The Badische Anilin und Soda Fabrik.....	854

Finland Customs Tariff, Changes in. (T.R.)	332
Fire-slay Goods, Use of Sugar in Manufacturing. (P) Palin	303
Pipes, Manufacture of. (P) Griffiths	1131
Fire-Extinguishing Compounds. (P) Martin	1129
Firework Factory, Report on Explosion at Pain's. (Majendie)	966
Fireworks, Manufacture of. (P) Stephenson	893
Firing Points of Explosives. (Munroe)	1063
Fish Manure. (Kellner)	87
Oil, Detection of, in Lined OIL. (Rudna)	974
Treating and Preserving. (P) Pursell	92
Fixing Agent, Magnesium Chloride as a. (Liesegang)	546
Fixing-bath, Properties of the Acid. (Lainer)	546
Silver in Old. (Lainer)	546
Flashing Point of Lubricating Oils. (Holde)	329
Of Lubricating Oils. (Martens)	902
"Flash Powder" Explosions. (Mitchell)	413
Flavin and its Preparation. (Soxhlet)	1125
Flavopurpurin, Colouring Matters from. (P) Murray. From The Farb. vorm. Meister, Lucius, and Bruning	854
Flax, Jute, and Hemp Fibre, Distinction between. (Lenz)	732
Floorcloth, Machinery for Printing. (P) Heyde	174
Machinery for Printing. (P) Ostlere and Strathern	174
Manufacture of. (P) Warburg. From Nuedel	1047
Florida, Camphor in. (Maiseh)	1151
The Phosphate Beds of. (T.R.)	565
Flood-dust Spelter, Iron in. (Jensch)	190
Fluids, Apparatus for Evaporating. (P) Chamberlain and Davis	1115
Apparatus for Induction of. (P) Morton and Thomson (illus.)	379
Apparatus for Treating Pulverulent Matters by. (P) Wise. From Solvay (illus.)	726
Fluorescein Chloride, Imide Compound of, and Colouring Matters therefrom. (P) Murray. From The Farb. vorm. Meister, Lucius, and Bruning	385
Fluorescent Blue. (Nietzki and others)	400
Fluorides, New Uses for. (Effront)	1055
Fluorindimes. (Fischer and Hepp)	1028
Fluorine, Colour and Spectrum of. (Moissan)	187
Preparation and Density of. (Moissan) (illus.)	186
Salts, formation of. (Netto)	182
Fluoroform. (Meslans)	646
Fluorspar, Use of in Metallurgy. (Foehr)	516
Fluxing Material. (P) Craven	77
Food, Combination of Animal Substances for Use as. (P) Johnston	404
Fariaceous, for Animals. (P) Bremier	92
Preparation and Combination of. (P) Johnston	818
Preparations. (P) Brunck and Rehnstrom	818
Preserving Articles of. (P) Batchelerie	1058
Preserving Articles of. (P) Douglas and Donald	538
Foods and Food Additives. (Crampton)	205
Sulphurous Acid in Preserved. (Brand)	404
Foodstuffs, Detection of Benzoic Acid in. (Mohler)	770
Forage, Culture of the Potato for. (Girard)	524
Foreign Trade in 1889, Our. (T.R.)	128
Forestry, International Congress on	1048
Formaldehyde, Estimation of. (Eschweiler)	116
Sodium Bisulphite, added to Gelatine-Bromide Emulsion. (Eder)	546
Formic Aldehyde in Photography. (Schmauss)	104
Formal-para-phenetidine	650
Fractional Distillation in Vacuo, Apparatus for. (Gautier)	653
France, Coal production in, during 1889. (T.R.)	339
Colouring Wm in. (T.R.)	334
Imports of Oils and Oil Seeds into. (T.R.)	775
Imports of Dyewoods into. (T.R.)	775
Manufacture of Tartaric Acid in. (T.R.)	1164
Mining Industry of. (T.R.)	669
Production of Cider in. (Soc. Arts J.)	529
Proposed Tariff Revision in. (T.R.)	828
Frangulin. (Thorpe and Robinson)	412
French and Foreign Competition in Senegal. (T.R.)	223
Front-Resisting Power of Building Stones. (Bauschinger)	1037
Fucose. (Guthrie and Tollens)	1052
Fucusaldehyde. (Bieler and Tollens)	956
Fucosol. (Bieler and Tollens)	274
Fuel, Apparatus for Combustion of. (P) Dinz (illus.)	381
Artificial. (P) Morris	796
Artificial. (P) Mowll	170
Artificial. (P) Myall. From Lancaster	728
Artificial. (P) Popplewell. From Cornhill	186
Artificial. (P) Stone	273
Artificial. (P) Wood	1118
Burning Liquid, in Furnaces. (P) Hadden. From Amersco	596
Furnaces for Burning Liquid. (P) Sahlstrom and others	1118
Manufacture of. (P) Besson	273
Producing Clean Gaseous. (P) Wilkinson	734
Production of Artificial. (P) Lemard and Hardman	1025
The Loomis Process for Making Gas for. (Oakman)	894

	PAGE
Fuels, The "Godillot" Furnace for Inferior. (Brull) (illus.) .	44
Fuller's Earth, Machine for Refining. (P) Sheppard .	273
Funnel and Measure for Liquids. (P) Brown .	43
Funnels or Reservoirs. (P) Payne (illus.) .	167
Furfural-Yielding Bodies from Wheat and Rye-Chaff. (Steiger and Schulze) .	1143
Furfuraldehyde and Pentagalactoses, Quantitative Estimation of. (Günther and Tollens) .	903
Presence of, in Commercial Alcohols. (Landet) .	1153
Furfuralphenylhydrazones .	902
Furfuryl Derivatives, New Relation of, with Sugars. (Maquenne) .	202
Furnace for Inferior Fuels, The "Godillot." (Brull) (illus.) .	44
For Refining Metals. (P) Alzucaray .	950
Furnaces and Grates. (P) Miles .	728
Burning Liquid Fuel in. (P) Haddan. From Amoroso .	586
Electrical. (P) Parker .	809
For Burning Liquid Fuel. (P) Sahlstrom and others .	1118
Rotating, for Calcining Ores. (P) Alley .	1041
For Quicksilver. (Eng. and Min. J.) (illus.) .	77
For Utilising Hydrocarbon as Fuel. (P) Dymond. From The Acrated Fuel Co. .	49
Metallurgical. (P) Plat .	867
Obtaining Uniform Products from Basic. (P) Pszczolka .	810
Regenerative Gas. (P) Casson .	627
Fusel Oil, Examination of. (Long and Lindeburger) .	537
Fuses and Detonators. (P) Ward and Gregory .	822
Fuses, Construction of Electric. (P) Ward and Gregory .	893
Electric. (P) Scott and Lawrence .	81
<b>G</b>	
Galunine. (Gautier and Monrgues) .	618
Galuctosediphenylhydrazones .	902
Galacetophenone, Producing Coloured Compounds of, on Fibres. (P) Johnson. From The Badische Anilin and Soda Fabrik .	500
Galicin, Ozokerite in. (Shotsky) .	597
Petroleum, Industry of. (T.R.) .	777
Gallopine Blue. (Knecht) .	55
Gallie and Tannic Acids, Bottinger's New Reaction for. (Smith) .	450
Acid. (Bottinger) .	955
Acid, Action of Reducing Agents on. (Bottinger) .	902
Acid, Note on. (Spence) .	1114
Acid, Oxidation of. (Bottinger) .	746
Gallotannic Acid. (Bottinger) .	955
Acid, Note on. (Spence) .	1114
Galls, Export of, from China. (T.R.) .	119
Galvanic Batteries. See Batteries.	
Galvanised Iron. (Pren) .	76
Galvanising Iron. (P) Greenway .	809
Iron and Steel. (P) Saunders .	195
Works, Treating Waste Pickle from. See Residues.	
Galvano-Plastic Deposits, Removal of. (P) Boulton. From Reinfield .	81
Gambier at Singapore. (J.R.) .	830
Products of Singapore. (T.R.) .	670
Gantter's Method for Estimating Tannin. (Procter) .	260
Method for Estimating Tannin. (Schroeder and Paessler) .	1157
Gas Analysis, Apparatus for. (Bedson) .	261
And Air Comminglers. (P) Poppewell. From Mitchell .	925
Apparatus for Carburetted. (P) Hall .	170
Apparatus for Generating and Enriching. (P) Howell and Smith .	850
Apparatus for Manufacturing Heating. (P) Kitson .	48
Apparatus for Manufacture of, from Air. (P) Fritz .	925
Apparatus for Manufacture of Water. (P) Briggs .	274
Apparatus for Producing Oil. (P) Lawson .	1118
Apparatus for Purifying Illuminating. (P) Andrews .	797
Balance. (Lux) (illus.) .	415
Burners, Incandescence. (P) Clamond .	797
Chemistry of the Dinsmore Process for Manufacture of. (Smith) (illus.) .	444
Detecting Sulphuretted Hydrogen in Coal. (Ledig) .	108
Estimation of Cyanogen in. (Leybold) .	979
Furnaces, Regenerative. (P) Casson .	627
Furnaces, Regenerative. (P) Siemens (illus.) .	1119
Generating and Consuming Combustible. (P) Love .	596
Generating Water. Siemens, and Producer. (P) Langer and Cooper (illus.) .	170
Generators. (P) Langer and Cooper (illus.) .	170
Generators for Carbonic Acid. (P) Chavasse .	859
Generator for Carbonic Acid. (P) Estcourt (illus.) .	860
Generator for Oil Lamps. (P) Robinson .	1025
Heating by, at Constant Volume. (Scheurer-Kestner) .	380
Heating Boilers by. (P) Imray. From Ware .	171
Inspector, Annual R-report of Massachusetts .	485
Manufacture, Ammonium Chloride from By-products of. (Dubose and Heuzey) .	614
Manufacture, Cyanogen in. (Leybold) .	923
Manufacture of. (P) Dinsmore .	924
Manufacture of. (P) Fergusson .	1024

Generator and Filter. (P) Herder.....	504	Welding-Pechny Process, Extension of the. (T.R.).....	672
Generator, Shavings for. (P) Herder.....	204	Wery's Apparatus for Heating Retort Furnaces. (Bremont).....	168
Vines after Treatment with Copper Salts. (Comboni).....	525	Woselsky's Resorcinol Colouring Matters. (Netzki and Detze).....	489
Attacked by Coleopterous Insects, in Tunis. (Leboulhène).....	635	White Lead, Manufacture of. (P) Brouner.....	630
Violet, Chrome. (Knecht).....	56	Manufacture of. (P) Condy.....	199
N. Acid, and Patent Blue. (Ullrich).....	384	Manufacture of. (P) Lake. From Tiblats.....	338
Viscosimeter for Observations of Oils. (Engler and Kunkler) (illus.).....	654	Manufacture of. (P) Thompson.....	630
Viscous Matters, Making Textile Threads from. (P) du Vivier.....	236	Production of. (P) MacIvor and others.....	630
Substances, Apparatus for Drawing off. (P) Sack.....	849	Wiborgh's Method for Analysis of Sulphur in Iron and Steel. (Cohen) (illus.).....	16
Vitriol, Reduction of Nitrous, by Coke. (Lunge).....	733	Wine and Alcoholic Liquors, Purifying. (P) Rousseau and others.....	757
Voltaic Batteries. See Batteries.....		Apparatus for Pasteurisation of. (P) Kuhn.....	880
Vote of Thanks to Chairman of London Section.....	585	Applying Antiseptic Agents to. (P) Boake and Roberts.....	1057
To Secretary of London Section.....	585	Detecting Colouring Matters in. (Weirich).....	974
Vulcanised Plastic Compounds. (P) Boulton. From Kiel.....	398	Detection of Noxious Mineral Substances in. (Liebermann).....	890
Vulcanising Rubber Articles. (P) Davis.....	631	Ferments, Preparation of. (Rommier).....	880
		From Dried Grapes, Nitrogen in. (Gazeneuve and Ducher).....	756
		Manufacture of. (P) Redfern. From Perscheid.....	1057
		Manufacturing Non-Alcoholic. (P) Dean.....	260
		Quinine. (Pharm. Zeit.).....	1143
		Wines and Spirits, the Bouquet of. (Rommier).....	816
		Colouring Matter of Red. (Heise).....	91
		Destroying Microbes in. (P) Spilker and others.....	319
		Determination of Tartar, Tartaric Acid, and Malic Acid in. (Schneider).....	1068
		Determining Amount of Sugar to be added to certain. (Mauwene).....	1055
		Estimation of Sugar in Sweet. (Borntrager).....	115
		Inorganic Salts contained in. (Schneider).....	1068
		Italian Customs Report on.....	1055
		Polarisation of. (P) Kuhn.....	1056
		Polarimetric Observations in Sweet. (Borntrager).....	115
		Testing Colouring Matter in. (P) Mathieu and Morfaux.....	403
		The Colouring Matter of. (Monnet).....	657
		Volumetric Estimation of Tannin in. (Roos, Casson, and Girard).....	556
		Wood, Apparatus for Cutting up. (P) Wiegner.....	819
		Behaviour of, at High Temperatures in Presence of Caustic Soda. (Tausch).....	883
		Bobbins, &c., Bleaching. (P) Greg.....	939
		Composition for Preventing Decay of. (P) McMahon.....	819
		Distillation, By-products of. (Vladesco).....	750
		Felt for Bandages. (P) Walcher.....	320
		Fibre and Pyridine Bases. (Hh).....	555
		Flexible Substitute for. (P) Thompson. From Heepe.....	1048
		Gum, Researches on. (Wheeler and Tollens).....	369
		Percentage of Cellulose in. (Papier Zeit.).....	1156
		Wood-Pulp Industry of Sweden. (T.R.).....	306
		Pulp Manufacture in Scandinavia. (T.R.).....	224
		Pulp, Preparation of. (P) Chesbrough. From Patoky.....	321
		Pulp, Qualitative Determination of Mechanical, in Paper. (Herzberg).....	1068
		Pulps, Manufacture and Bleaching of. (P) Ramsey.....	211
		Rendering Highly Inflammable. (P) Gridley.....	1119
		Spirit, Estimation of Acetone in. (Vignon).....	659
		Staining and Mottling. (P) Prosser and Carter.....	304
		Vessels for Corrosive Substances. (P) Turner.....	379
		Wood-Wool, Apparatus for Making. (P) Evenstad and Senstad.....	819
		Wolfamite, Technical Analysis of. (Setlik).....	109
		Wood and Animal Fibres, Washing. (P) Ambler.....	856
		And other Textile Fibres, Cleansing. (P) Eastwood and Ambler.....	610
		Apparatus for Carbonising. (P) Silberberg and Detring.....	1034
		Apparatus for Dyeing. (P) Mason.....	612
		Apparatus for Making Wool. (P) Evenstad and Senstad.....	819
		Bleaching by Sodium Hydrosulphite. (Dommergue).....	804
		Chroming of. (Knecht and Ward).....	58
		Dyeing, Mordants Applicable in. (Gardner).....	286
		Extracting Pure Neutral Grease from. (P) Lahusen and Feuerlein.....	521
		Fat. (Langbeck).....	376
		Freeing from Grease. (P) Pinagel.....	286
		Obtaining Lanolin from Wash-Waters of. (P) Lahusen and Feuerlein.....	1046
		Producing "Green-Mordanted." (Knecht).....	60
		Producing Mineral. (P) Kennedy.....	1116
		Scouring and Washing. (P) Portella.....	174
		Separating, from Rabbit Skins. (P) Puech.....	498
		The Chroming of. (Scurati-Manzoni).....	732
		Treating and Scouring. (P) Eyre and Hopkins.....	290
		Woolen Stuffs, Prevention of Stripiness in Dyed. (Walther).....	56
Wads and Psilomelanes, The. (Gorgeu).....	508		
Wall-paper, Decorating. (P) Strahan.....	1035		
Rollers and Blocks for Printing. (P) Clegg and Kirby.....	804		
Wash, Drying Distillers' Spent. (P) Larsen.....	757		
Washes for Animals. (P) Angus and Craig.....	813		
Material for. (P) Carr.....	398		
Washing Composition. (P) Bowden and others.....	814		
Compounds. (P) Asenough.....	68		
Water, Analysis of, for Manufacturing Purposes. (Vignon).....	656		
Analysis of, to Determine necessary Amount of Anti-Incineration Agent. (Vignon).....	655		
Apparatus for Evaporating. (P) Newton and Quiggin.....	481		
Apparatus for Making Aerated. (P) McEwen (illus.).....	403		
Apparatus for Producing Fresh, from Sea Water, &c. (P) Ferguson.....	44		
Apparatus for Purifying. (P) Allen and Bowers.....	727		
Apparatus for Purifying. (P) Anderson.....	818		
Apparatus for Purifying. (P) Desmiaux.....	882		
Apparatus for Purifying. (P) Wright.....	849		
Apparatus for Purifying and Cooling. (P) Shapsen.....	727		
Apparatus for Softening. (P) Brown.....	406		
Apparatus for Softening and Filtering. (P) Wright.....	378		
Apparatus for Syruping Aerated. (P) McEwen (illus.).....	404		
Berenger and Stirling's Method of Softening (Kahnmann).....	1065		
-Gas. See Gas.....			
-Glass, Production of. (P) Boulton. From Sievert (illus.).....	623		
Determination of Chlorine in. (Hazen).....	110		
Determination of Nitric Acid in Drinking. (Spiegel) (illus.).....	806		
Determination of Superphosphates in. (Stoklasa).....	969		
Distilling Sea or other. (P) Newton and Quiggin.....	43		
Electrical Purification of Contaminated. (Webster).....	1093		
Electrolysis of. (P) Latchinoff.....	196		
Estimating the Oxygen Dissolved in. (Thresh).....	327		
Estimation of Nitrites and Nitrites in. (Ormundy and Cohen).....	973		
Examination of. (Fischer).....	93		
Filtration of. (P) Gerson.....	406		
Filtration of. (P) Hawksley.....	818		
Means of Purifying. (P) Davis.....	406		
Obtaining Fresh from Salt Water. (P) Stevenson.....	43		
Proportion of, to HCl Formed by Igniting Mixtures of H, O, and Cl. (P) Hautefeuille and J. Margottet.....	184		
Purification of. (P) Crocker.....	819		
Purifying Apparatus. (P) Carrod.....	319		
Purifying Sea. (P) Lewes.....	480		
Removal of Bacteria from Drinking. (Sedgwick).....	641		
Schulze-Tiemann's Method for Determining Nitric Acid in. (Schmidt).....	972		
Softening. (P) Archbutt and Deiley.....	406		
Softening and Clarifying. (P) Gittens.....	1116		
Softening and Filtering under Pressure. (P) Easton and Carrod.....	319		
Softening and Purifying. (P) Harrison.....	167		
Sterilisation of River, by Mine Water. (Breneman).....	1058		
Treatment of Sea. (P) Bramley.....	594		
Waters, Determination of Lithium in Mineral. (Waller).....	1066		
Determining the Hardness of Natural. (Neugebauer).....	970		
Materials for Purifying Foul. (P) Jones.....	883		
Treatment of Foul. (P) Nicholson and Palmer.....	883

Zinc, Action of, on Dilute Sulphuric Acid. (Pullinger) .....	946
And Copper, Volumetric Determination of. (Donath and Hattensaur) .....	554
And Lead in Burnt Gases from Blast Furnaces. (Vita) ...	512
And Mercury, Double Cyanide of. (Dunstan) .....	211
And Nickel, Separation of. (Alt and Schulze) .....	328
Apparatus for Extraction of. (P) Rabache .....	1135
Blende, Roasting. (Minor) .....	76
Corrosion of, in Contact with Brick. (Iron) .....	1087
Determination of, as Pyrophosphate. (Boyd) .....	973
Dust, Valuation of. (Klemp) .....	968
Estimation and Separation of, in Presence of Iron and Manganese. (Ribau) .....	823
Estimation of. (Minor) .....	972
Estimation of Metallic, in Zinc Dust. (Minor) .....	1153
Estimation of, in its Ores. (Coda) .....	968
Extraction of. (P) Rabache .....	1135
Extraction of, by Electrolysis. (P) Abel. From Siemens and Halske .....	396
Tin, and Copper, Obtaining Electrically. (P) Seegall .....	520
Or Spelter, United States New Tariff for. (T.R.) .....	425
Ores, Examination of. (Minor) .....	417
Ores, Treatment of. (P) The Alkaline Reduction Syndicate and Cunningham .....	741
Oxide and Alkaline Earths, Characteristics of. (Brugel- mann) .....	766
Oxide, Occurrence of Arsenic in. (Stromeyer) .....	766
Permanganate of. ....	409
Plates for Lithographic Purposes, Preparing. (P) Brockle- hurst .....	630
Removal of Silver by Means of. (Rossler and Edelmann). ..	1133
Titration of. (Moldenhauer) .....	108
Use of Ferric Hydrate in Determination of. (Minor) .....	103
Vapours, Apparatus for Condensing. (P) Gutzner and Kochler .....	949
Volumetric Estimation of. (Blum) .....	969
Zinc-White Industry in Germany. (T.R.) .....	428
Zirconium, Obtaining Salts of. (P) Inray. From MacKean..	941

## INDEX OF NEW BOOKS.

	PAGE		PAGE
Air, Practical Treatise on Examination of. With Appendix on Illuminating Gas. J. A. Wanklyn and W. G. Cooper. . . . .	980	Patentees' Manual, The. J. and J. H. Johnson . . . . .	662
Analysis, Electro-Chemical. E. F. Smith . . . . .	904	Physikalische Technik. Dr. J. Erick's. Sechste umgearbeitete und vermehrte Auflage. Von Otto Lehmann . . . . .	904
Handbook of Quantitative. J. Mills and B. North . . . . .	117	Pocket Book for Pharmacists, Medical Practitioners, Students, &c. T. Bayley . . . . .	423
And Research, Report on, during 1886-89, in the Cent. Chem. Lab. of Italian Customs. R. Nasini and V. Villavecchia . . . . .	1074	Principles of General Organic Chemistry. E. Hjelt. Translated from the German Edition by J. Bishop Tingle . . . . .	826
(Organic) of Potable Waters. J. A. Blair . . . . .	826	Prometheus. O. N. Witt . . . . .	117
Anleitung zur Chemisch-Technische Analyse Organischer Stoffe. Von F. M. Horn . . . . .	332	Report on Analysis and Research, 1886-89, in the Cent. Chem. Lab. of Italian Customs. R. Nasini and V. Villavecchia . . . . .	1074
Asbestos, Its Properties, Occurrence, and Uses. R. H. Jones . . . . .	1163	Science, The Threshold of. C. R. Alder Wright . . . . .	1074
Assaying, A Textbook of. C. and J. J. Beringer . . . . .	117	Sugar Analysis for Refineries, &c. A Handbook of Instruction in. F. G. Wiechmann . . . . .	1163
Beet, Culture of the Sugar, and Manufacture of Beet Sugar. H. W. Wiley . . . . .	980	Sugar-Beet, Culture of the, and Manufacture of Beet Sugar. H. W. Wiley . . . . .	980
Chemie des Steinkohlentheers mit Besondere-r Berücksichtigung der Künstlichen Organischen Farbstoffe. G. Schultz . . . . .	220, 423	Sugar Manufacturers and their Chemists, a Handbook for. G. L. Spencer . . . . .	423
Chemisch-Technische Analyse. J. Post . . . . .	117, 774	Steinkohlentheers, Die Chemie des, mit Besonderer Berücksichtigung der Künstlichen Organischen Farbstoffe. Von G. Schultz . . . . .	220, 423
Organischer Stoffe, Anleitung zur. F. M. Horn . . . . .	332	Technisch-Chemisches Jahrbuch, 1888-89. R. Biedermann . . . . .	116
Chemisch-Technisches Repertorium. Von Emil Jacobsen . . . . .	332, 826, 1163	Technological Dictionary of Insurance Chemistry. W. A. Harris . . . . .	662
Chemistry, a Treatise on. Sir H. E. Roscoe and C. Schorlemmer . . . . .	661	Theerfarben mit Besonderer Rücksicht auf Schädlichkeit und Gesetzgebung Hygienisch und Forensisch-Chemisch Untersucht. Von Th. Weyl . . . . .	558
A Technological Dictionary of Insurance. W. A. Harris . . . . .	662	Theoretischen Chemie, Grundzüge der. Von Lothar Meyer . . . . .	1164
Dictionary of Applied. T. E. Thorpe . . . . .	219	Threshold of Science, The. C. R. Alder Wright . . . . .	1074
Principles of General Organic. E. Hjelt. Translated from the German by J. Bishop Tingle . . . . .	826	Treatise on Chemistry, A. Sir H. E. Roscoe and C. Schorlemmer . . . . .	661
Dictionary of Applied Chemistry. T. E. Thorpe . . . . .	219	Electro-Metallurgy, A. W. G. McMillan . . . . .	1074
Of Insurance Chemistry, A Technological. W. A. Harris . . . . .	662	The Evaporation of Saccharine, Chemical and other Liquids by the Multiple System in Vacuum and Open Air. J. Foster . . . . .	662
Electro-Chemical Analysis. By E. F. Smith . . . . .	904	Untersuchungen aus der Praxis der Gährungs Industrie. Emil C. Hausen . . . . .	1074
Electro-Metallurgy, A Treatise on. W. G. McMillan . . . . .	1074	Verunreinigung der Gewässer, eine Denkschrift im Auftrage der Fluss-commission des Vereins zur Wahrung der Interessen der Chemischen Industrie Deutschlands. K. W. Jurisch . . . . .	661
Evaporation of Saccharine, Chemical, and other Liquids by the Multiple System in Vacuum and Open Air, Treatise on the. J. Foster . . . . .	662	Waters, The Organic Analysis of Potable. J. A. Blair . . . . .	826
Farbenreactionen der Kohlenstoffverbindungen Die. E. Nickel . . . . .	904	Year Book of the Scientific and Learned Societies of Great Britain and Ireland . . . . .	558
Gährungs Industrie, Untersuchungen aus der Praxis der. E. C. Hausen . . . . .	1074		
Gasanalytische Methoden. Von W. Hempel . . . . .	558		
Grundzüge der Theoretischen Chemie. Von Lothar Meyer . . . . .	1164		
Handbook for Sugar Manufacturers and their Chemists. G. L. Spencer . . . . .	423		
Irwell and its Tributaries, The River. (A Monograph on River Pollution). G. E. Davis and A. R. Davis . . . . .	904		

Eyre and Spottiswoode,  
East Harding Street, London, E.C.

# ·LIST OF MEMBERS.

## A

Abbott, John, Braemar House, Lancaster Gate, Hyde Park, W.  
 Abel, Sir F. A., 40, Cadogan Place, London, S.W.  
 Abraham, A. C., Stanley Rock, St. George's Mount, New Brighton (Journals); and 87, Bold Street, Liverpool.  
 Acland, Sir H. W., Radcliffe Library, Oxford.  
 Adam, A. Learmouth, 40, Sir Michael Street, Greenock, N.B.  
 Adam, J. B., 172, Leith Walk, Edinburgh.  
 Adams, M. A., Ashford Road, Maidstone, Kent.  
 Adams, J. W., 74, Oxford Street, Regent Road, Salford, Manchester.  
 Adamson, G. P., Easton, Pa., U.S.A.  
 Addie, J., Langloan Ironworks, Coatbridge, N.B.  
 Adkins, H., Chemical Works, Smethwick.  
 Adriance, John S., 1, East 55th Street, New York, U.S.A.  
 Affleck, J., Mill House, Woolton, near Liverpool.  
 Aikman, Charles M., 183, St. Vincent Street, Glasgow.  
 Aikman, Thomson, jun., 5, Prince's Square, Glasgow.  
 Aitken, Dr. A. P., 57, Great King Street, Edinburgh.  
 Aitken, J. B., Gerard's Fold Chemical Works, Widnes.  
 Akitt, Thomas, 3, Victoria Road, Lenzie, N.B.  
 Albright, G. S., The Elms, Park Road, Edgbaston.  
 Albright, W. A., Mariemont, Birmingham.  
 Alexander, J. O., Plantation Leonora, Demerara, British Guiana.  
 Alexander, W. T., 20, Booth Street, Moseley Street, Manchester; and Crummock Bank, Victoria Crescent, Eccles.  
 Allan, Jno., 12, Woollaston Road, Harringay, N.  
 Allbright, W. B., c/o Halstead & Co., 196-202, Forsyth Street, New York, U.S.A.  
 Alldred, C. H., 33, Crisp Terrace, Upper Park Road, Plumstead Common, Kent.  
 Allen, A. H., Sydenham Cottage, Park Lane, Sheffield.  
 Allen, G. J., 27, Bolton Road, Pendleton, Manchester.  
 Allen, J., 164, Upper North Street, Poplar, London, E.  
 Allen, R. L., Roseleigh, Heaton Chapel, near Stockport.  
 Allen, Walter S., 13, Beacon St., Boston, Mass., U.S.A.  
 Allen, Wm., Edenholme, Bournemouth, Hants.  
 Allen, W. H., Peniuslar Laboratory, Detroit, Mich., U.S.A.  
 Allender, G. M., Stammerham, Horsham, Sussex.  
 Allhusen, A., Gateshead-on-Tyne.  
 Allhusen, Wilton, 102, Quay Side, Newcastle-on-Tyne.  
 Allibon, G. H., Seaview, Litherland Park, near Liverpool.  
 Alliot, J. Bingham, Messrs. Manlove, Fryer, Alliot, and Co., Nottingham.  
 Alpar, Agop, Smyrna, Asia Minor.  
 Alsberg, M. (Sondheim, Alsberg, & Co.), P.O. Box 2437, New York, U.S.A.  
 Anderson, Geo. B., Victoria Square, Felling-on-Tyne.  
 Anderson, John, c/o The Alkaline Reduction Syndicate, Ltd., Hebburn-on-Tyne.  
 Anderson, J. M. T., Explosives Co. Ltd., Stowmarket, Suffolk.  
 Anderson, Robt. T. R., 618, Gallowgate Street, Glasgow.  
 Anderton, G. H., Howendyke, Howden, Yorks.  
 Andrew, W. B., Gavinburn, Old Kilpatrick, Dumbartonshire.  
 Andrews, C. W., Mass. Inst. of Technology, Boston, Mass., U.S.A.  
 Angell, J., 81, Ducie Grove, Oxford Street, Manchester.  
 Angus, James, Thorncliffe Collieries, Chapelton, Sheffield.  
 Angus, W. Mathwin, St. John's Leather Works, Newcastle-on-Tyne.  
 Annandale, J. H., Polton, Midlothian, N.B.

Annisson, R. H., 16, Water Lane, Tower Street, London, E.C.  
 Ansdell, G., 45, Courtfield Road, South Kensington, S.W.  
 Ansdell, T. C., Kearsley Cottage, Farnworth, Bolton.  
 Archbold, Dr. George, 250, West 14th Street, New York City, U.S.A.  
 Archbutt, L., 11, Charnwood Street, Derby.  
 Arding, Francis, 5, Jeffreys Square, St. Mary Axe, London, E.C.  
 Armstrong, Dr. H. E., Central Institution, Exhibition Road, London, S.W.  
 Armstrong, Rt. Hon. Lord, Newcastle-upon-Tyne.  
 Ash, T. E., 4, Saltram Place, Citadel Road, Plymouth.  
 Ashburn, Wm., 36, Portman Street, Whalley Range, Manchester.  
 Ashwell, H., Woodthorpe Grange, Sherwood, Nottingham.  
 Ashwell, J. H., Woodthorpe Grange, Sherwood, Nottingham.  
 Ashwell, Jno. R., 111, Waterloo Crescent, Nottingham.  
 Ashworth L., Sunny Lea, St. Anne's-on-Sea, Lancashire.  
 Atcherley, Dr. R. J., 80, Elsham Road, Kensington, W. (for Journals); and 11, Queen Victoria Street, E.C.  
 Atkins, S. R., Market Place, Salisbury.  
 Atkinson, A. J., 44, Loudoun Square, Cardiff.  
 Atkinson, R. W., 44, Loudoun Square, Cardiff.  
 Attfield, Dr. J., Ashlands, Watford, Hertfordshire.  
 Aubrey, W. H., 19, Ryecroft Road, Courthill, Lewisham, S.E.  
 Auer, H., Appleton Lodge, near Widnes.  
 Auerbach, Dr. C. G., 25, Friesenheimer Strasse, Ludwigschafen a/Rhein, Germany.  
 Austen, Prof. Peter T., New Brunswick, N.J., U.S.A.  
 Aykroyd, H. E., Ashwell, Toller Lane, Bradford, Yorks.

## B

Babington, F. W., Inland Revenue Laboratory, Ottawa, Canada.  
 Babington, Percival, c/o Percy Hirst, Elmfield, Rotherham, Yorks.  
 Bachmann, Dr. Irvin A., Georgia Chemical Works, Augusta, Georgia, U.S.A.  
 Bailey, Edwin M., Laboratory, Pumpherson Oil Co., Ltd., Midealder, N.B.  
 Bailey, Wm., The Terrace, Oaken, near Wolverhampton.  
 Bailey, Dr. G. H., Owens College, Manchester.  
 Bailey, Thos., 25, High Street, Hull.  
 Bailey, Richard D., City Brewery, Gloucester.  
 Bailey, Dr. T. L., University College, Brownlow Street, Liverpool.  
 Bailey, W. H., Albion Works, Salford, Manchester.  
 Bailey, Walter P., 8, South Park, Ilford, Essex.  
 Bainbridge, Herbert A., Malvern Hall, Solihull, near Birmingham.  
 Baker, E., Stoneleigh, Eastern Avenue, Reading, Berks.  
 Baker, Harry, Vicarage Road, Langley Green, near Birmingham.  
 Baker, John T., Easton, Pa., U.S.A.  
 Baker, W. G., Garden Wharf, Church Road, Battersea, London, S.W.  
 Baker, Theodore, E. C. Powder Co., Green Street Green, Dartford, Kent.  
 Bald, J. H., Braddock, Pa., U.S.A.  
 Baldwin, W. A., 169, West 97th Street, New York City, U.S.

- Ball, Jos. P., 4533, Frankford Avenue, Philadelphia, Pa., U.S.A.
- Ballard, E. G., 1, Eversley Park, Chester.
- Ballantyne, H., 260, Renfrew Street, Glasgow.
- Bamber, H. K., 5, Westminster Chambers, Victoria Street, London, S.W.
- Banister, H. C., 31, Dale Street, Liverpool.
- Bank, Arthur J., Freehold Street, Fairfield, Liverpool; and c/o Block Co., Morpeth Dock, Birkenhead (for Journals).
- Banner, Samuel, 4, Ivanhoe Road, Liverpool.
- Bannister, R., The Laboratory, Somerset House, London, W.C.
- Bannister, W., Victoria Lodge, Cork, Ireland.
- Barbour, T. F., 26, Robertson Street, Glasgow.
- Barclay, H., Rose Hill, Harrington, Cumberland.
- Barchey, Thos., 17, Bull Street, Birmingham.
- Bardsley, Robt., c/o Jewsbury and Brown, 44, Downing Street, Manchester.
- Barnes, H. J., Phoenix Chemical Works, Hackney Wick, E.
- Barnes, J., Marl Terrace, Acerington, Lancashire.
- Barnes, Jonathan, Buckton Vale, near Stalybridge.
- Barnes, R. L., Phoenix Chemical Works, Hackney Wick, E.
- Barr, J., Dinting Vale, Glossop.
- Barret, E. L., 192, Belsize Road, Hampstead, N.W.

# THE JOURNAL

OF THE

# Society of Chemical Industry:

## A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 1.—Vol. IX.]

JANUARY 31, 1890.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2/6.]

### The Society of Chemical Industry.

#### Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond	1888—1889.

### COUNCIL FOR YEAR ENDING JULY, 1890.

*President:* Sir Lowthian Bell, Bart., F.R.S.

#### Vice-Presidents:

R. Forbes Carpenter.	S. H. Johnson.
Prof. F. Clowes, D.Sc.	Ludwig Mond.
Sir J. Neilson Cuthbertson.	Dr. Hugo Muller, F.R.S.
Prof. James Dewar, F.R.S.	Dr. W. H. Perkin, F.R.S.
Jas. Duncan.	Dr. Edw. Schanck, F.R.S.
Dr. John Evans, F.R.S.	Prof. W. A. Tilden, F.R.S.

#### Ordinary Members of Council:

L. Archbutt.	B. E. R. Newlands.
S. B. Boulton.	Jno. Pattinson.
Jno. Brock.	Jno. Spiller.
Jno. Calderwood.	E. C. C. Stanford.
Alexander M. Chance.	J. C. Stevenson, M.P.
A. E. Fletcher.	A. Norman Tate.

With the Chairmen and Secretaries of Sections.

#### Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

#### Honorary Foreign Secretary:

Dr. Ferdinand Hurter.

*General Secretary:* Charles G. Cresswell.

#### Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

### THE JOURNAL.

#### Publication Committee:

##### The President.

Sir F. A. Abel, F.R.S.	Prof. A. K. Huntington.
A. H. Allen.	F. Hurter, Ph.D.
G. H. Bailey, D.Sc., Ph.D.	Ivan Levinstein.
Joseph Bernays, M.I.C.E.	Prof. R. Meldola, F.R.S.
H. Brunner.	Ludwig Mond.
W. Lant Carpenter.	E. K. Muspratt.
Prof. Frank Clowes, D.Sc.	B. E. R. Newlands.
W. Y. Dent.	C. O'Sullivan, F.R.S.
Prof. Jas. Dewar, F.R.S.	John Pattinson.
John Heron.	W. H. Perkin, Ph.D., F.R.S.
D. B. Hewitt, M.D.	Sir H. E. Roscoe, M.P., F.R.S.
David Howard.	John Spiller.
Prof. J. J. Hummel.	A. Norman Tate.
p. 639.	Thomas Tyrer.

#### Editor:

Watson Smith, University College, London, W.C.

#### Assisted by the following Staff of Abstractors:

S. B. Asher Aron.... IV., IX.	Chas. A. Kohn..... } Gen. Chem.

D.Sc..... } Gen. Chem.	V. H. Veley, M.A. .... Gen. Chem.
	A. Wingham..... X.

### NOTICES.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOOD, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

#### LIST OF MEMBERS ELECTED, 23rd JANUARY, 1890.

Aykroyd, H. E., Ashwell, Toller Lane, Bradford, Yorks, dyer.

Bachmann, Dr. Irvin A., Georgia Chemical Works, Augusta, Georgia, U.S.A., chemist and manager.

Barrett, Arthur A., 46, Mount Pleasant, Liverpool.

Bayay, Aug. de, Victoria Brewery, Melbourne, Australia, brewer.

Bott, Dr. Wm., Raffles Institution, Singapore, science lecturer.

Brindley, G. F., Silverdale, Douglas Road, Handsworth, Birmingham, chemical engineer.

Brown, Edw., Russian Steam Oil Mills, 22, Kourlandsky Street, St. Petersburg, analytical chemist.

Brown, R. J., M.Sc., 3, Oakfield Terrace, Davenport, near Stockport, chemical teacher.

Carr, Isaac, Gas Works, Widnes, engineer and manager.

Chapman, Alf. C., 23, Easton Buildings, Gower Street Station, N.W., analytical chemist.

Church, Elihu D., jun., 124, Milton Street, Brooklyn, N.Y., U.S.A., mining engineer.

Critchley, C. A., Victoria Works, St. Helens, Lancashire, colour manufacturer.

Fielding, Patrick J., 1, Vesta Place, Blackrook Road, Cork, pharmaceutical chemist.

Grevel, Hermann, 33, King Street, Covent Garden, W.C., publisher.

Hagen-Schow, J. A., 4, Stanley Villas, Rutland Road, Hammersmith, W., brewing chemist.

Lacey, E. C., 126A, Bermondsey Street, London, S.E., manufacturing chemist.

McKillop, Jno., Puloh Brani, Singapore, metallurgist.

Mellon, E. L., Glenside, Clayton Bridge, near Manchester, chemist.

Merek, E., Darmstadt, Germany, manufacturing chemist.

Moffatt-Johnson, J., The Birches, Midealder, N.B., chemist.

Morgan, Jno. Jas., 6, Tredegar Road, Ebbw Vale, Mon., chemist and assayer.

Peers, T. H. P., 184, Old Kent Road, London, S.E., druggist.

Pomroy, Dr. Chas. T., 266, Halsey Street, Newark, N.J., U.S.A., ink manufacturer.

Rosell, Claude A. O., United States Patent Office, Washington, D.C., U.S.A., chemist.

Rothband, W. S., 61, Elizabeth Street, Cheetham, Manchester, chemical manufacturer.

Sewell, Parker, 11, Alice Street, South Shields, analytical chemist.

Shaw, Jno., Eariston, Uddingston, near Edinburgh, chemist.

Smith, Harry, 33, Withington Road, Whalley Range, Manchester, chemist.

Smith, Harry E., 133, 26th Street, Milwaukee, Wis., U.S.A., assistant chemist.

Sowerby, Thos. H., Sherwell, Dartmouth Place, Blackheath, S.E., soap manufacturer.

Stevenson, J. Shannan, Jarrow Chemical Works, South Shields, chemical manufacturer.

Wakayama, Y., Yayegakicho Nedzu Tokyo, Japan, chemist.

Watson, Eric E., 13, Kingsmead Road, Oxtou, Birkenhead, chemical student.

White, Jos. W., Halebank, near Widnes, iron merchant.

Wilson, W. W., Chirnside Villa, Droylsden, Manchester, chemical assistant.

#### CHANGES OF ADDRESS.

Aitken, Dr. A. P., 1/o Clyde Street; 57, Great King Street, Edinburgh.

Baker, Harry, 1/o Titford Road; Vicarage Road, Langley Green, near Birmingham.

Bank, A. J., 1/o Rawlins Street; Freehold Street, Fairfield; and (Journals) c/o Bloek Co., Morpeth Dock, Birkenhead.

#### SESSION 1889-90.

1890.

Feb. 3rd:—

Messrs A. H. Allen and W. W. Staveley. "On the Properties and Applications of Metallic Compounds of the Phenols."

Mr. Watson Smith. "A New Method of Hardening Steel for Cannon and Projectiles."

Prof. S. M. Losanitsch. "On Bromanil."

March 3rd:—

Dr. H. Schlichter. "Analysis of Textile Fibres and Fabrics."

Dr. L. T. Thorne. "A Review of the Methods of producing Oxygen commercially."

March 31st (instead of April 6th—Bank Holiday):—

Triennial Election of Committee and Officers of Section. Nominations to be sent to the Honorary Secretary on or before Monday, March 17th.

Dr. W. S. Squire. "Note on a Machine for a Methodical Separation of Solids and Liquids."

Dr. S. Rideal. "Note on the present Monetary Value of Available Oxygen."

May 5th:—Mr. Wm. Webster. "The Electrical Treatment of Sewage."

June 2nd:—Dr. W. S. Squire. "The Artificial Production of Cold theoretically and practically considered."

July:—Annual General Meeting in Nottingham.

Meeting held Monday, 6th January, 1890.

MR. DAVID HOWARD IN THE CHAIR.

### PEROXIDE OF HYDROGEN: ITS PRESERVATION AND COMMERCIAL USES.

BY C. T. KINGZETT, F.I.C., F.C.S.

PEROXIDE of hydrogen is at once an extraordinary and a most interesting compound, extraordinary as regards the modes of its preparation and interesting on account of the facility with which it loses oxygen. It is this facility of decomposition which renders it so valuable as an oxidising and bleaching agent, but at the same time has in the past militated against its more extensive adoption for such purposes. For a long time it has been recognised that if means could be devised of preserving this substance from spontaneous decomposition to any considerable extent, its market value would enormously increase, for while it is without rivals as an antiseptic oxidising agent, it is also of a perfectly innocuous character and free from all objections. Peroxide of hydrogen has been with me the subject of much study, and as is well known, I have for many years been engaged in the manufacture of compounds containing it or capable of yielding it in association with other substances under definite circumstances.

In connection with this part of my subject it may be mentioned by way of a summary statement that, when terpenes are subjected to oxidation by air, oxygen, or ozone, there is formed an active organic compound of the nature of a peroxide which remains dissolved in the hydrocarbons used for producing it, and when the product is placed in

contact with water, peroxide of hydrogen is formed and passes into aqueous solution by some reaction of which the following equation may be accepted as giving, if not the actual reaction, at least an approximately correct representation:—

The compound  $C_{10}H_{16}O_2$  (soluble camphor) is uncrystallisable and accompanies the peroxide of hydrogen in the aqueous solution.

There is a great similarity between this chemical change and that by which the peroxide of hydrogen is made by the other well-known process, viz., by the action of dilute acids upon peroxide of barium. Taking sulphuric acid as representative of all acids, it may be said that when peroxide of barium is exposed to the presence of sulphuric acid and water, the following change results:—

It will be understood of course that I have here resorted to the use of somewhat abnormal formulæ in order to clearly represent what I believe to be the nature of the chemical change, and I have intentionally expressed peroxide of hydrogen by the formula  $H_2O$  for reasons to which I am about to make reference.

The constitution of peroxide of hydrogen is generally graphically represented as follows:—

Fig. 1.

which would signify that each atom of oxygen is diatomic, and is directly combined with one atom of hydrogen. But the character of the substance and its facility of decomposition are altogether opposed to such a view, and in a short paper which was communicated to the British Association some years ago\* I gave expression to my opinion that in a strictly chemical sense it is rather to be regarded as oxygenated water or as an oxide of water. That is to say, oxygen is to be regarded as either a triad or a tetrad in valency, and the one atom is combined with the other which alone is directly combined with both atoms of hydrogen, thus:—

Fig. 2.

Fig. 3.

This view accords with the general sense of chemical opinion that when in a compound an atom of one substance is directly combined with another such atom, the combination is weak, and there is consequently facility of decomposition. This view is also supported by certain observations which were made by M. Berthelot, showing that when oxide of silver is placed in contact with peroxide of hydrogen, the amount of oxygen set free is only equal to that contained in the peroxide of hydrogen employed, the residual matter containing the whole of the silver and oxygen originally present in the oxide of silver, but redistributed, so that there results a mechanical mixture containing one-third of the silver in the reduced metallic state, and the oxygen, in combination with the balance, in the form of sesquioxide of silver. To put the matter in another way, the chemical change is not to be expressed by the equation—

but rather by this one—

Further confirmation is lent to my views by the very existence of ozone which may be viewed as a form of triatomic oxygen.

To pass on now to the chief part of my subject, it should be first stated that, while peroxide of hydrogen is undoubtedly very prone to suffer decomposition, the statement which is made in most text-books to the effect that dilute solutions are immediately decomposed on ebullition, is radically wrong. It is, therefore, all the more to be regretted that this method has been advocated for estimating the strength of the liquid. As a matter of fact, dilute solutions may be concentrated by evaporation, although, of course, there is an attendant loss of oxygen.

Mr. G. E. Davis at one time† published some figures illustrating the rate of decomposition of a solution of peroxide of hydrogen, but before reproducing these it may be as well to explain the meaning of a description, which is common enough in commerce; I refer to the strength of such solutions as expressed in volumes. A 10-volume solution of peroxide means a solution which is capable of yielding of itself, by perfect decomposition, 10 times its own volume of gaseous oxygen at the ordinary temperature and pressure.

Now, Mr. Davis worked with a 10-volume solution, so that 100 cc. yielded 1,000 cc. of oxygen when fully decomposed; in other words, the solution contained 3.04 per cent. by weight of real peroxide of hydrogen, and was capable of yielding 1.43 per cent. by weight of oxygen gas.

On August 2, 1878, the strength of the solution was 9 volumes.

"	"	31	"	"	"	"	8.4	"
"	"	24	"	"	"	"	8.0	"
"	Sept.	1	"	"	"	"	7.9	"
"	"	24	"	"	"	"	7.8	"
"	Oct.	24	"	"	"	"	7.2	"

I shall presently furnish other figures from my own experience, but may at once state that the rate of decomposition is by no means constant. It varies with the temperature, exposure to light, and the impurity of the solution. Sometimes a solution will be found to suffer even less change than that observed by Mr. Davis, while at others it undergoes complete decomposition in course of a few weeks, and more or less suddenly. The observations I have made will serve to explain to some extent the reasons for this capricious character.

To those engaged in the manufacture of peroxide of hydrogen it is well known that the presence of a little ether restrains the decomposition, and, indeed, in his experiment, Mr. Davis found that by adding a little ether to the solution on October 24th it had not deteriorated in strength two months later in the year. The action of the ether is not, however, always to be depended upon, and its presence is apt to lead to danger, particularly if added to solutions which are likely to be exported to hot climates, while it is sometimes objectionable on other grounds also. I have suggested that the restraining influence of ether is to be found in the fact that it also generates peroxide of hydrogen by atmospheric oxidation. It may also act by reason of its volatility, thus generating a vapour which exercises a gentle restraining pressure over the solution.

Dr. G. Gore has shown, in a paper recently communicated by him to the Royal Society, that when chlorine water is exposed to light, the chemical changes that occur in one distinct period result in the production of hydrochloric, hypochlorous, and chloric acids, and that at a later stage a further formation of hydrochloric acid takes place, while at the same time peroxide of hydrogen is formed in solution. Under the influence of prolonged sunlight, the whole of the oxygen of the hypochlorous and chloric acids united with water to form the peroxide, and that substance subsequently entered into combination with the whole of the hydrochloric acid and formed a definite "solution compound" which is represented by the formula  $2 HCl, H_2O_2$ . This is the more interesting because it is well known that, as a bleaching agent, chlorine acts intermediately by the decomposition of

\* See Chem. News, Vol. XLVI., 141.

† Chem. News, Vol. XXXIX., p. 221.

water, and it is nascent oxygen that is credited by chemists with the bleaching effects thus attainable. It is, after all, not impossible that the effects are due to the formation of peroxide of hydrogen, a substance which is, as a bleaching agent for woollen and some other goods, rapidly displacing bleaching powder in public estimation.

I now propose to call attention to the decomposition and preservation of peroxide of hydrogen as influenced by the presence in it of other substances in a state of solution.

I may premise that I was led to this investigation by my desire to put upon the market a series of disinfectant solutions for use by surgeons and others which should be characterised, in common with "Sanitas" disinfecting fluid, on the one hand by the presence of a definite quantity of peroxide of hydrogen, and on the other hand by containing a definite amount of some one or other of a series of reliable antiseptic and germicidal substances. Some medical men prefer one antiseptic, and others exercise other selections, but I insist upon the necessity of using any such germicides, in association with a potent oxidising agent capable of chemically destroying the toxic products which result from the growth of bacteria and other micro-organisms in suitable media. It is these toxic products that are more to be dreaded than the micro-organisms themselves, and no system of disinfection is perfect, from a chemical point of view, which overlooks the necessity for their chemical change or destruction.

After surmounting many difficulties, into the details of which I need not enter here, I was faced with what proved to be the greatest obstacle of all, viz., the liability of such solutions when prepared, to undergo decomposition, and that sometimes with almost explosive violence.

As I felt there was no royal road to success, and no scientific clue to a means of overcoming the trouble, I determined to study the matter in a constructive sense, and to ascertain, over long periods of time, the preservative or destructive influences which might be exercised by dissolving, in solutions of peroxide of hydrogen, definite percentages of various substances, and the results which have been tabulated for convenience this evening represent some of the results.

In this series of observations, 50 cc. of peroxide of hydrogen solution was used in each experiment, the solution being of such strength that 100 cc. was capable of liberating from an acidified solution of potassic iodide such an amount of iodine as required 730 cc.  $\frac{N}{10}$  hypo. solution ( $Na_2S_2O_3$ ) to decolourise it.

0.5 gram. of the several substances indicated in the first column was added to as many quantities of the peroxide. The mixtures were placed in well-stoppered bottles freely exposed to the light of the laboratory, and the strength of the solutions, in terms of cc.  $\frac{N}{10}$  hypo. was determined as above explained from time to time.

The experiments were started on 30th November 1887.

From a study of the results it will be seen that none of the substances which were tested materially promoted the stability of the peroxide, although several nitrates and chlorides exercised a limited restraining influence. It will be further seen that very many of the added substances materially facilitated the decomposition of the peroxide.

In the somewhat disjointed series of observations next to be described and the results of which are expressed in Table II., the substances indicated in the first and second columns were added to so many solutions of 100 cc. each, except in the case of chloroform, in which 50 cc. peroxide was employed together with the amount of absolute alcohol as indicated for the purpose of dissolving the added chloroform.

The original testings of the solution are expressed in the table. The solutions containing the added substances were placed in stoppered bottles and gently shaken from time to time.

It will be seen that one standard solution did not suffer any decomposition in course of 31 days, while in another instance a standard solution suffered change to the extent of nearly 16 per cent. in 29 days; a third standard solution

lost 74 per cent. in 22 days and the whole of its  $\text{H}_2\text{O}_2$  within 84 days; in the fourth series of observations the standard solution lost 95 per cent. in 36 days. The rule was that the greater the warmth of the weather the greater was the loss in a given time.

It will also be observed that alcohol, glycerin, chloroform, absolute phenol, ether, acetic acid, and potassic bisulphate exercised a restraining influence.

The next series of observations which are tabulated in Table III. were based upon the results of the preceding experiments, and were at once more systematic and much more extended in point of time, lasting over 405 days so far as the results now communicated are concerned, while some of the solutions are even yet in course of observation.

One per cent. by weight in volume of the added substances was employed, and the observations were commenced on August 28th, 1888. Originally 100 cc. of the  $\text{H}_2\text{O}_2$  which was employed, required 1,296 cc.  $\text{N}_{10}$  hypo. solution.

The testings were made by taking out 5 cc. of the solutions, making up to 50 cc. with added water and using 5 cc. of the diluted solution for the purpose of decomposing acidified KI solution, after which the iodine set free was determined in the usual manner.

The phenol, beta-naphthol, and thymol mixtures all became discoloured (brown), the last-named one being least discoloured.

The original solution of peroxide was exactly neutral, but gave a precipitate with solution of barium chloride.

The following substances were imperfectly dissolved:  $\beta$ -naphthol, thymol, and salutar.

The results speak for themselves, and it is only necessary to point out the very distinctive value of the following substances in restraining the decomposition of the peroxide, viz., alcohol and ether.

Many other of the added substances were more or less effectual, in common with which it is seen that sulphuric acid was of some value.

On April 14th, 1889, a fresh series of observations were made, using a solution of peroxide of hydrogen which was slightly acid to test paper.

With sulphuric acid it gave a slight precipitate of sulphate of barium.

With barium chloride it did not yield a precipitate. Ammonia caused in it a flocculent precipitate which was to a large extent soluble in ammonium chloride. With hydric-disodic phosphate it gave a slight precipitate. By way of strength 100 cc. liberated such an amount of iodine from acidified potassic iodide as required 1,540 cc.  $\text{N}_{10}$  hyposulphite of sodium for complete reaction.

Quantities of 100 cc. each were taken, and to them was severally added 1 gm. of the substances indicated in Table IV.

Again, it will be observed that alcohol and ether each materially preserved the solutions of peroxide of hydrogen from decomposition. So also did camphoric acid, camphor and menthol, while thymol, the influence of which is very comparable with that exhibited in the previous series of experiments, comes out better in comparison with all these substances.

The observations which are still in hand have not extended however over such a protracted period as those which are expressed in Table III.

Viewing the whole results of the third and fourth series of observations it is perhaps to be inferred that the comparative success attained in the third series was due to the employment of an *exactly neutral* solution of peroxide, for although sulphuric acid exercises a restraining influence on its own account, it facilitates decomposition in comparison with the repressive action of ether, alcohol, thymol, camphoric acid, camphor and other substances.

It was upon the basis of these and other results of a like character, and having regard to the mode of preparation of the crude article, that I have been enabled to devise satisfactory means for preserving peroxide of hydrogen as presented in commerce from any appreciable loss of strength over reasonable periods of time.

It remains for me to state that these means have been patented, and none of the substances which I have indicated

as being useful for repressing the natural decomposition of peroxide or for preserving it from such change, can be employed by others than the Sanitas Company, Limited (to whom I have assigned my rights), or their licensees.\*

In those cases in which it has been ascertained that certain substances facilitated the decomposition of peroxide of hydrogen there is a great range of activity, and in the operations of bleaching these facts admit of practical utilisation. As a rule, some alkaline compound such as ammonia or carbonate of sodium is used to promote the operations, but they act too violently and cause much loss of oxygen, thus adding to the expense of the process. For many such purposes therefore, these alkaline compounds may in future be well replaced by some of the compounds referred to in my tables, and of which borax affords a striking example.

Apart from the previously well-known oxidising properties of peroxide of hydrogen, it was proved for the first time by some experiments, of which an account was presented by me to the British Association in 1876, that this substance exhibits striking antiseptic effects and is capable, even when present in very small proportions, of entirely arresting processes of fermentation which are originated by living organisms. The antiseptic properties of the substance were subsequently confirmed by the observation of Guttman and Fränkel in Germany. Later still, some similar observations were made by M. Baldy, who concluded that peroxide of hydrogen is in no respect inferior to carbolic acid.

M. Paul Bert and M. Regnard confirmed my own earlier experiments, they showing (Comp. Rend. 94, 1383—1386) that an extremely dilute solution of peroxide of hydrogen prevents the fermentation of glucose by the agency of yeast, prevents mycdermic growth in red wines, lactic fermentation in milk, and the putrefaction of albumen, &c. On the other hand they found that it was incapable of arresting the changes which are induced by soluble non-organised ferments, such as diastase. This distinction is of importance, because if peroxide of hydrogen be employed for internal administration, it affords a guarantee that the presence of that substance in the human system will not arrest nor interfere with the many assimilative and other processes which are carried on by means of ferments of the pancreatic type.

It was therefore to be expected that this compound would be found of peculiar benefit for the treatment of wounds and for general use in the practice of antiseptic surgery, and that anticipation has been amply realised in the practice of M. Baldy, M. Regnard, and particularly that of M. Péan in the hospital of St. Louis. It has been demonstrated beyond question that all wounds which are treated with peroxide of hydrogen progress well, healing by first intention, all discharges being healthy in character and free from odour. Chronic ulcers are similarly treated with the same successful results, so also cases of gangrene, fetid suppurations, and bad ozonic discharges.

M. Péan performed many important operations in an atmosphere impregnated with peroxide of hydrogen instead of carbolic acid, and M. Baldy employed gauze and wool which had been soaked in peroxide, for placing in contact with wounds by means of bandages where prolonged contact was desirable. He also found that it might, with safety, be used as an injection for washing out cavities.

Dr. A. W. Harlan, in a paper read before the American Dental Society (Dental Record, November 1882), strongly recommended the use of peroxide in the treatment of blind alveolar abscesses and pyorrhea alveolaris, because the rapid evolution of oxygen gas effects a thorough evacuation of the pus without creating any undesirable after effects.

M. Landolt, of Paris, and Dr. J. E. Adams, of the London Hospital and Royal London Ophthalmic Hospital, have both used peroxide of hydrogen with great success in cases of purulent discharge from the conjunctiva (see British Medical Journal, December 9th, 1882).

Since October 1885, Professor Hofmooke has employed peroxide with the greatest advantage in the treatment of diphtheria, while for syphilitic and cancerous swellings and wounds generally, it is now in everyday use by many of the most eminent surgeons at home and abroad.

\* See this Journal, 1889, p. 1,000; and 1890, p. 101.

In a recent paper (read before the King's County Medical Association, February 5th, 1889, during a discussion on diphtheria: see "Gaillard's Medical Journal" for March 1889) Dr. E. R. Squibb, of Brooklyn, says:—"If diphtheria be at first a local disease and be auto-infections—that is, if it be propagated to the general organism by a contagious virus located about the tonsils, and if this virus be, as it really is, an albuminoid substance, it may and will be destroyed by this agent upon a sufficient and sufficiently repeated contact."

Peroxide of hydrogen never fails to thoroughly cleanse all mucous surfaces. It not merely exhibits the power of destroying pus and other such products by oxidation, but it is admitted by the most reliable bacteriologists to be an exceedingly powerful germicide, ranking perhaps in this respect next to biniodide of mercury, while, as distinct from that substance, it is quite non-poisonous.

As all air-breathing animals depend upon atmospheric oxygen for their very life, it stands to reason that for all diseases that are in any way dependent upon defective oxidation, peroxide of hydrogen is the best natural remedy, being a solution of oxygen in chemical combination with the elements of water.

Valuable as is peroxide of hydrogen alone, it becomes still more valuable in its properties when associated with other reliable antiseptics and germicides as presented in the series of bactericides to which I have made general reference in an earlier part of this paper.

With respect to the uses of peroxide of hydrogen for bleaching, a summary statement will suffice. It has been used and is being used with success for bleaching wool and woollen goods, silk (particularly tussah), ostrich feathers, living and dead human hair, sponges, ivory, bone, wash leather, horn, gut, wooden articles, and so forth. It may also be employed for bleaching cotton, fine yarns, and textiles, but not so successfully as for woollen goods. For such bleaching purposes tanks or vessels of wood, glass, or earthenware are employed. Metallic vessels have to be avoided. The general method of procedure consists in freeing the articles from dirt and grease by washing them with ammonia water or with dilute soda or carbonate of soda, and after having thoroughly rinsed them out they are immersed in the solution of peroxide of hydrogen, sometimes used of 10-vol. strength and at other times of only 2-vol. strength; frequently ammonia or some other alkali is added to the solution of peroxide in order to facilitate the bleaching.

The operation of bleaching is generally carried out at a temperature of about 30°–50° C., heat being employed in the form of steam carried through a leaden coil immersed in the bath.

As I have previously pointed out, the addition of an alkali in order to hasten the effect is made at the expense of using an extra amount of peroxide, and in my opinion borax would replace it to advantage where it is necessary to employ any such agent for facilitating the operation.

## DISCUSSION.

The CHAIRMAN said that the practical application of peroxide of hydrogen depended in very many cases on the possibility of retaining the solution at approximately the same strength for a considerable period. Every chemist knew, however, that under ordinary circumstances it was a most unstable body. The restraining action on the decomposition of hydrogen peroxide exhibited by the various substances mentioned by Mr. Kingzett was extremely curious and surprising. He would have expected that the more unstable the associated body the more rapid would be the decomposition of the peroxide of hydrogen; but this had proved to be by no means the case. The useful adaptation of oxygen depended, broadly speaking, on the careful study of the conditions of its activity, and everything which threw light upon that important subject was of the highest scientific and industrial value.

Professor CLOWES said that the paper had suggested one or two points of theoretical importance upon which he would be glad to have some further information. It was well understood that the valency attributed to the atom of a chemical element was disputable, and therefore he was not surprised to find suggestions for altering the valency of oxygen. But Mr. Kingzett had assumed, apparently, that it might be either triad or tetrad instead of dyad. Probably he had already assigned his reasons for that assumption, but if he could now give them again, members of the Section would probably be glad to hear them: he (Dr. Clowes) did not understand how the oxygen atom could be represented as triad in the molecule of ozone. In the table written on the blackboard, too, Mr. Kingzett indicated the change occurring between hydrogen peroxide and silver oxide, and introduced the formula AgO<sub>3</sub>. He would be glad to know whether Mr. Kingzett had any definite grounds for assuming the existence of that unfamiliar substance.

Dr. SQUIRE had at one time had a great deal to do with hydrogen peroxide, and found that, provided that it were properly made to begin with, ether preserved it very well, in fact, left nothing to be desired. But there was peroxide and peroxide, and these remarks applied only to a tolerably pure article. The amount of ether required was small, about one ounce to the gallon being sufficient to preserve the peroxide for six months at least. At all events, peroxide so preserved was sold under the name of Robare's Aureoline in thin flat glass bottles, which would burst with the slightest internal pressure, and in this form remained for months in hairdressers' shops with perfect safety. In what way the ether acted, he did not know; certainly not, as Mr. Kingzett suggested, in consequence of its vapour exercising a certain pressure. If a slight pressure were all that is required, this would be supplied by the partial decomposition of unprotected peroxide in closed vessels. The pressure thus produced ought to stop further action, but this was not found to be the case. In reference to the author's remarks as to the strength of the solution, he would point out that it was not only in America that a five-volume solution of hydrogen peroxide was sold as 10 volumes. By treatment with permanganate or bichromate of potassium 10 volumes were obtained, of course, but half of it came from the decomposing agent and the other half from the peroxide itself. He believed that by the universal custom of the trade the label 10 volumes meant evolving, not containing, 10 volumes.

Dr. STEINHART wished to know whether Mr. Kingzett had tested his solutions to which alcohol had been added, and whether the latter, in the presence of so powerful an oxidising agent as peroxide of hydrogen, had not been oxidised to aldehyde, and finally to acetic acid. It was well known that an acid solution was more stable, and it occurred to him, therefore, that the stability of the author's hydrogen peroxide in this case might be due to the presence of acetic acid and not to the alcohol.

Dr. S. RIDEAL thought it would be interesting to be able to compare the different monetary values of oxygen, free and combined. He would therefore ask the author to give the meeting, if he could, some data as to the monetary value of oxygen as an oxidising agent. They would thus be able to judge whether bleaching as performed by hydrogen peroxide would be cheaper or dearer than when due to bleaching-powder or other oxidising agent.

Mr. KINGZETT, in reply, said that the reason he had represented oxygen as either triatomic or tetraatomic was that it could not possibly be diatomic. If it were diatomic the two oxygen atoms in the peroxide of hydrogen molecule would be equally associated with each atom of hydrogen, and consequently of equal stability, which was not the case, seeing that one atom only was so easily dissociated. Chemical common sense clearly showed that the two atoms could not have the same combined value in peroxide as the one atom of oxygen had in a molecule of water. It followed, therefore, that it must be either triatomic or tetraatomic. He inclined to the view that it was triatomic, because it undoubtedly was so in ozone. As to the chemical equation on the slate which had been referred to in course of the discussion, he wished to disclaim all responsibility for it. It was due to the French chemist, Berthelot, and represented the analytical results of his investigation as communicated to the *Académie des Sciences*.

Dr. Squire's remarks were especially valuable, because of his large experience in the manufacture of peroxide of hydrogen; and he had hit the right nail on the head when he said that the action of the ether depended largely upon how the hydrogen peroxide itself had been prepared. Therein laid the crux of the matter. If it were carelessly prepared, if it were either acid or alkaline in character, or if it contained certain impurities, no agent would prevent it from decomposing within certain limits; but if it were properly prepared, as it could be by those who understood the subject, then the substances which he had mentioned were capable of preserving it from material loss of strength for 12 months or more. With respect to the strength of hydrogen peroxide solutions he knew that there were manufacturers here, dishonest enough—he used the term advisedly, for it was dishonesty—to represent that their five-volume solutions were 10-volume solutions, relying on the quantity of oxygen as obtained by the so-called permanganate test. In America they always did so; but of course that could be got over by testing the solution with acidified iodide of potassium, and estimating the iodine thus set free in the usual manner.

Dr. Steinhart had inquired as to the specific chemical action of alcohol, and had suggested that the stability of the peroxide, as preserved by that substance, was due to the formation of acetic acid and the production thereby of an acid reaction. That could not be, for if Dr. Steinhart would refer to Table 3 he would find that in the first two experiments (which were made with standard solutions) he had added 1 per cent. of sulphuric acid to one of them on the 46th day, and it would be seen that the restraining influence of the acid reaction was expressed by the fact that on the 405th day the unprotected solution had lost 83 per cent., whereas the protected solution (which for 46 days was maintained under the same conditions) had, owing to the addition of the sulphuric acid, lost only 60 per cent. Therefore the restraining action of the sulphuric acid was about 23 per cent. It would also be seen from the same table (experiment No. 6) that acetic acid certainly exercised an even greater restraining influence than sulphuric acid; so much so, that on the 405th day the loss was only 50 per cent. Therefore it had a greater effect *per se*. Whether the effects of the sulphuric and acetic acids were to be regarded as due merely to "acid reaction," or were to be viewed in their individual characters, there could be no question but that alcohol certainly restrained very much more than did either the one acid or the other, as was revealed by the figures submitted. It was therefore absolutely incredible that the preservative effect of alcohol is due to the generation of acetic acid therefrom.

Lastly, as to the monetary value of oxygen in its various forms, he was sorry not to be able to give any exact data.

Air was cheap enough, but it was not capable of producing those decolourising and oxidising effects which had to be obtained in the commercial bleaching of silk, cotton, paper, bone, hair, &c. Atmospheric oxygen, therefore, had no value in relation to such applications, nor was pure oxygen any more valuable, so far as he knew. Hydrogen peroxide, and that alone, had a distinct value for such purposes. Common air and oxygen were of no utility, either, for antiseptic purposes, whereas peroxide of hydrogen had a most pronounced value in that respect. With regard to bleaching-powder he had stated in his paper that peroxide of hydrogen was, so far as Germany and France were concerned, believed to be rapidly replacing bleaching-powder for bleaching woollen, silk, and other goods, partly in consequence of the destructive effect of chloride of lime on the tissues of such materials, and also because peroxide of hydrogen gave better results. He believed that the adoption of peroxide would follow more largely in England in time; and as to the comparative cost, the results which had been published justified him in saying that peroxide of hydrogen was not more expensive than bleaching-powder for such purposes, while its production was constantly being cheapened and its effective action increased.

## ON A NEW METHOD OF COLOUR ANALYSIS BY MEANS OF THE TINTOMETER.

BY J. W. LOVIBOND.

I HAVE to-night to describe and illustrate by a series of experiments a new instrument for the analysis and registration of colour.

I do not now propose to discuss the theoretical laws which govern the question of colour, having endeavoured as far as possible to keep myself free in my experiments from any undue bias to any particular theory.

The instrument and method to which I refer is a new means of impartially judging the various colours; for recording the factors of colour which combine to form any given colour; and a system for registering the same, even in the most complicated combinations, and the most delicate shades as well as in the deepest tints which exist in nature.

The illustrations which I propose to submit will represent work already done, and those cases where the application is commercial, have already become routine in the industries to which they apply.

*Description of Apparatus.*—The apparatus which is before you now on the table may be divided into two essential parts.

First, an optical instrument which gives two fields of view under equal optical conditions free from errors arising from unequal side lights, from the influence of adjacent bodies, and from any difference of colour-perception, which may exist between the right and left eye of the observer. The grave extent of error arising from the last cause will be seen on reference to the first set of columns in Table No. 3 on "Neutral Gray," where out of nine observers, only No. 1 has the colour-perception practically equal for both eyes; No. 2 equal for red and blue, but varies in yellow as 10·0 to 7·5; No. 3 varies in red as 10·0 to 9·0; in yellow, 10·0 to 7·5; in blue, 10·0 to 14·0; whilst No. 6 pronounced six observations as tinged with green; these are equally divided between the yellow and blue columns.

The second part is the standard scale, of which I shall speak presently.

The instrument consists of two tubes, A, A, side by side, divided by a central partition B, terminating at the centre of the eye-piece C in a knife edge, which, being inside the range of vision, is not noticed, so that light, entering the openings D D at the opposite end, passes in equal quantities

up each tube to the eye of the observer, giving a clear view of any opaque bodies which may be placed outside, or of transparent bodies inside the tubes.

The sides and central partition are grooved in order to hide the edges of the measuring glasses, and of the gauged

vessels for containing fluids. Stops are placed at convenient distances to cut off light reflected from the sides, and the size and shape of the apertures D can be altered by means of diaphragms to suit small or irregularly shaped samples.

**The Standard Scale.**—The second essential part is the standard scale, which consists of sets of coloured glass slips, all the glasses of each set being of the same colour, but each glass differing in depth of colour, the difference being in degrees of equal value throughout the scale.

In all comparisons of a single colour, the starting point has been taken as a pure white. The standard white used as a background for the glasses is pure lime sulphate for small surfaces, and for large surfaces, as for the reflectors, the smooth side of Messrs. Chance's opal glass, but whichever is used should be quoted.

I may here say that a comparison of pressed lime sulphate against snow shows no free colour in the lime sulphate, which is only .25 of a degree of neutral gray less white than the snow itself.

**Colour Scale.**—The relative positions of two-tenths, one degree, ten degrees, and twenty degrees are marked on the colour scale of primaries before you.

The equality of the scale can be tested in the lantern by placing a single glass of 20 degrees value on each side, and then making 20 degrees by any combinations from other parts of the scale as  $12 + 7 + 1$  equals  $3 + 8 + 9$ .

**The Unit.**—In the early days of the instrument, before the extent of its application for analytical purposes was fully realised, the necessity of dividing the colour scale into degrees of equal value before reliable work could be done, was evident. The starting point and value of these degrees were questions of the greatest importance and anxiety.

It was decided to fix upon as a starting point a definite degree of colour, the addition of which should be perceptible in the deeper shades, and dividing this degree into tenths and hundredths for the lighter shades, where the perception is keener, thus building up the scale by successive additions of equal value.

It will be seen that the starting point for each colour was arbitrary, that the value of the degree in each scale was equal throughout its entire length; but the impure colour in the glass then available made the fixing of a unit of common value for each primary colour almost hopeless.

A better quality glass, and more recent work, has, however, developed a possible basis for equalising the value of the unit for the three primary colours, red, yellow, and blue, and which are alone found necessary for most analytical work, and even holds out a hope of constructing a colour nomenclature with some degree of scientific accuracy.

I am aware that the colour in my primary standards, red, yellow, and blue, are not pure, but as they are the purest yet obtainable, and as by their means most of the colours in nature are measurable, I will ask that, for the purpose of illustration only, they may be considered as the three primary colours in glass.

**The Neutral Gray.**—The new departure is founded on the fact that neutral gray under certain known conditions is always made by a combination of 1 red, 1.2 yellow, and 2.4 blue in the original scales, and these proportions hold good at all depths. Then, by assuming these combining values of red, yellow, and blue to be the units of their respective colours, a simple relationship of equality between these three primaries is established, at least so far as the production of neutral gray is concerned.

Having established this common equivalent as a unit of colour in reference to neutral gray, by removing the yellow

equivalent a normal purple is left, made up of one equivalent of red and one of blue. By removing the blue equivalent a normal orange is left, made up of one equivalent of red and one of yellow. By removing the red equivalent a normal green is left, made up of one equivalent of yellow and one equivalent of blue.

Further, by placing 10 normal orange on each side of the screen, and adding a single degree of red to one side, and a single degree of yellow to the other, we have a 10 normal orange + 1° red, and a 10 normal orange + 1° yellow. Test this further with higher differences, as 5 on each side, and also with normal purple and normal green.

If binary colour is taken to be the sum of any two colours composing it, then any departure from the normal towards either primary can be accurately measured and described.

When a colour is composed of the three primaries, the units of neutral gray may be deducted as such, and the balance looked upon as free colour. Let us see how this works out by matching a sombre colour, such as brown paper, on the screen, by, say, 5 red, 6.3 yellow, and 4.4 blue. The equation may be written thus:—

$$\begin{array}{rcccl} & \text{R.} & \text{Y.} & \text{B.} & \text{N. G.} & \text{R.} & \text{Y.} \\ \text{Brown paper} & 5 & + 6.3 & + 4.4 = & 4.4 & + 0.6 & + 1.9; \end{array}$$

the latter part of the equation, 4.4° neutral gray, .6° of free red, and 1.9° free yellow, is an accurate description, and conveys an intelligible idea and record of the colour itself in this particular brown paper. Test this further by separating the free colour from the neutral gray. The method is available for the measurement of all sad-coloured bodies.

It also follows that, by the constant addition of neutral gray tints, a scale of equal degrees, ranging from white to black, may be established, and available for measuring the penetrating power of light.

Some precautions are necessary in selecting the proportion of primary colours for the composition of a true neutral gray; for instance, a person whose sight is abnormally strong or weak, even for a single primary, would never agree with an average selection, and this difficulty is increased when the abnormal condition applies to one eye only, as then each eye gives a distinctly different reading. The colour of the light must also be considered, as that from a blue sky, a dull sky, or a white cloud gives different results. The angle at which the daylight is taken has also an influence, the light gaining in red as the instrument or reflector declines from the perpendicular to the horizontal.

The proportions of primary colours for the neutral gray standard I have been dealing with is the result of observations taken in the open air, under a dull gray sky, with light as nearly perpendicular as possible, reflected from Messrs. Chance's opal glass, and is the average of 324 observations made by nine persons of my own staff, none of whom are colour-blind in the ordinary sense of the word, but all have more or less abnormal perceptions for one or more primaries in one of their eyes. I have not, however, removed any of the observations from the table of averages on this account.

A reference to the Table No. 3 will show that of the 324 observations, 130 were pronounced neutral gray, 91 slightly tinged with yellow, 80 with blue, and 23 with red. In no case had the observer a knowledge of what he was judging, and the judgments were frequently checked up and down

**Conclusion.**—In submitting this apparatus and method to your judgment, I am fully conscious that there must be many questions which time and more exhaustive work will elucidate, but I am not conscious of having hidden a weakness or exaggerated a strength, and feel sure that when the weaknesses are pointed out, they will act as a spur to further investigation. And in conclusion I wish gratefully to acknowledge the assistance received by me from many quarters; it will be impossible for me to enumerate all, indeed, in some instances I have no knowledge even of the names of gentlemen who have made valuable suggestions.

I am, however, specially indebted to Mr. H. Le Neve Foster, who worked out the method of quantitative estimation of carbon in steel; to Mr. T. Jobson, jun., of the Stocksbridge Works, near Sheffield, who overcame a difficulty in steel solutions of a reddish tinge; to Professor Hummel, of the Yorkshire College, Leeds, who suggested a method of bringing surfaces uneven in texture or colour to a suitable condition for comparison by throwing them out of focus with a lens at the eye-piece; to Dr. Knecht, of the Technical College, Bradford, for some comparisons in Turkey reds; to Mr. Boverton Redwood for co-operation in working out standards of colour for petroleum and cocoa-nut oils; to Dr. Munro, of the Downton College of Agriculture, for investigation into the method of making ammonia estimations, and for some special work on the colour of waters. The fine divisions in the standard scale is mainly the work of one of my daughters.

The working out of the neutral gray equation is the direct result of conversations with Professor Crookes, Professor Church, and Captain Abney, greatly aided by the brilliant lectures of the latter at the Society of Arts last session.

#### DISCUSSION.

The CHAIRMAN said that the subject of the paper was one of very wide interest, and capable of most important practical application. All chemists had to do with the

judging of colours, and all had a profound conviction of the perfection of their individual colour sense. Everyone present knew how delicate and difficult a matter it was to hint to a friend that his eyesight was not quite what it should be. With regard to the sense of sight, everyone considered himself perfect. He happened to have a number of relatives so far colour-blind as to be capable of imagining emeralds to be rubies, and *vice versa*. In all his experience in this direction, however, he had never met with a colour-blind woman, and did not believe that there was one. He would appeal to Mr. Lovibond on that point.

Mr. LOVIBOND said that he could agree with the Chairman's experience to this extent, that the only absolutely non-colour-blind person he had ever met was a woman.

The CHAIRMAN, continuing, said it was certain that as a rule women's eyes were far more accurate than men's. We ought to recognise the fact that a great many of us were more or less colour-blind with respect to certain tints; and if chemists in particular did so they would save a great deal of inaccurate work. He believed that it was in that room that Dr. Tidy had related his experiences in testing the average eye for accuracy. He could not recall the exact figures, but he remembered that a very small percentage of those tried could, for instance, sort out twenty shades of brown with an approximation to accuracy. Nevertheless, it was possible by careful training to greatly develop the power of the eye in this respect. To do so one must have accurate instruments and methods; and in Mr. Lovibond's apparatus and his method of gauging the different depths of colour, there seemed to him to be the means of training the eye to the work which the eyes of chemists were called upon to do. The matter was one well worthy the study not only of those to whom it was a subject of special importance, as to those engaged in dyeing, but of every chemist. They had to thank the Royal Institution for the loan of the lantern, and Mr. Heath for attending to exhibit the various colours on the screen.

Mr. BOVERTON REDWOOD was glad to have an opportunity of bearing testimony to the value for certain technical purposes of the instrument which Mr. Lovibond had taken so much trouble to exhibit and explain to the meeting. In connexion with the class of products with which he had to deal, it had been his lot for 20 years past to be almost daily engaged in chromometrical determinations, and consequently when Mr. Lovibond brought the tintometer under his notice some two years ago, he examined it with great interest. He had already had the opportunity of explaining, in that room, the principles of construction of the instrument with which, in the petroleum trade, they were in the habit of determining the colours of some of their products. That instrument had certain defects; and he had never found it well adapted for the registration of the colour of such oils as were employed for lubricating purposes. He had suggested, therefore, that there was an opening in that direction for such an instrument as the tintometer, and had gladly concurred in Mr. Lovibond's proposal that they should together endeavour to arrange a scale of standards suited for commercial use in the lubricating oil trade. He might say that in his laboratory for nearly two years past they had been in the habit of testing with the tintometer and recording the colour of a two-inch stratum of every sample of lubricating oil submitted to them, and there had thus been established a numerical scale of colour which already possessed some significance. They had of course experienced difficulties at times in consequence of the variable character of the daylight available—difficulties which all who were in the habit of working in London would appreciate. He did not refer to such exceptional cases as the darkness which had recently enveloped the city; but apart from such cases as that, Londoners had to work under atmospheric conditions which would afford Mr. Lovibond food for serious study after the more transparent atmosphere of Salisbury. He had reason to hope that at no distant date some artificial light equivalent to ordinary daylight, or capable of being employed alternatively, with some definite correction, might be provided. In that case the tintometer would come more largely into use than under present conditions. The experience they had had of the use of artificial light that evening was not encouraging; and, as one who had had some experience in the use of the instrument by daylight, he was bound to say that the impressions to be derived from the demonstrations just given were less favourable than those which would result from a short use of the instrument by ordinary daylight.

Mr. W. THORP felt grateful to Mr. Boverton Redwood for the encouragement conveyed by his concluding remarks. He had often to experience the difficulties due to the great peculiarities of what we were pleased to call daylight in London. It was no uncommon thing for a part of his work to be set aside for days, or even weeks, in consequence. Referring to the Chairman's remarks, he thought that any who had a short experience of a colour works would soon have any ideas of the perfection of their own eyesight knocked out of them. There were certain men at the works with which he was connected who had especially good eyes for certain colours, and when an examination of those particular colours was required it was done by those men. He himself had, he thought, a good eye for some colours, but there were others that he would not dream of judging. Under these circumstances the instrument before them ought to prove valuable. It would certainly be useful in giving a numerical value for depth of colour. He was not so clear as to its value for giving an exact representation of tone or tint, especially as it seemed to him, judging from the experiments just made under artificial light, that the tints produced by the mixtures of glasses were not what could be called *pure* colours. He believed, indeed, that Mr. Lovibond had referred to that point in his paper, and had said that they were not pure. It was often a matter of great importance to decide whether a colour was rich or poor, and how the instrument would deal with such a point as that he could not say. But while looking at the pieces of glass exhibited, a horrible doubt occurred to him as to their permanence, and he would be glad to know from the inventor whether he had considered that. People were very apt to think that coloured glass was permanent, yet probably most of those present had seen specimens of glass which had

begun their existence as colourless, and which before long had acquired an appreciable colour. He remembered seeing some glass which in 18 months had attained an intensity which would be represented on the scale before them by at least 2 degrees. If changes increasing or diminishing in depth, or varying, were to be feared, it would be a great impediment to the application of such instruments. How such a difficulty was to be met he did not see, but it was certainly a point worthy of careful consideration.

Dr. ALDER WRIGHT said that there were one or two points upon which he would be glad to have further information. In the first place, he did not understand what was meant by one, two, or three degrees. Did it mean that the glass was, for example, tinted with one, two, or three grains respectively of some colouring material per pound? Secondly, how far were the colours which were transmitted through the glasses mono-chromatic? In other words, if the glasses were viewed through a spectroscope, would one get a single line as the absorption spectrum, or a large proportion of bands at other parts of the spectrum? If there were any considerable proportion of other colours, it would be difficult to ensure that any combinations of glasses would give even approximately pure colours. He supposed it would be almost improper to inquire what the materials were with which the glasses were tinted. But if the author could give any information which would tend to show that a scale could be reproduced with accuracy at a future period, it would be of considerable interest to all possible users of the instrument.

Mr. FRIESE-GREENE wished to ask the author whether he had taken into consideration the effect due to the surfaces of the glasses used. It was obvious that as he increased the number of glasses in building up his colours, he would get more surfaces and, consequently, more reflection due to the breaking up of light all along the different media. His own experience in photography led him to think that this was a point which might be of considerable importance in the case of the instrument under notice. Again, it was well known that the eye in going from one colour to another always carried with it as it were the tone of the first colour; and not only so, but there was a kind of opposition set up by the retina endeavouring to neutralise the colour. Consequently, if the eye passed quickly from one colour to another, there was produced on the retina a mixture of the first colour or tint with the second. That was a matter which ought to be taken into consideration. It might be met by the observer going into the dark until the tone was neutralised, and then looking at the colour.

Dr. L. THORNE said that he had had one of Mr. Lovibond's tintometers in practical use for some time, and could fully corroborate Mr. Redwood's remarks as to the advantages to be derived from it. He had used it for estimating colour in oils, and also with regard to the colours of more or less bleached natural products, and had found it valuable in either case. Referring to what he might call the optical part of the instrument, he considered it a great advance on the apparatus hitherto used. Getting the one absolute field split up as it were by means of the wedge-shaped division, so that with the same eye one could get at the same focus the two fields in equal physical condition, enabled one to obtain an estimation of colour much more accurately than by any other process. As to the permanency of the standard colours, no doubt Mr. Lovibond would have something to say. But assuming that point to be satisfactory, he could strongly corroborate what had been said as to their value for future work. A colour having once been matched, the standards required for it could be noted, and the colour could be reproduced with absolute accuracy at any future time. He had not had a large range of colours to work with, but those which he had tested he had found to be matchable with ease; occasionally a very bright tint would be a little awkward to match, but not often. To him the point of special novelty in the paper was the portion relating to the production of neutral grays. It was a matter of the greatest interest from the theoretical point of view that the grays could be made up from those three standard colours, and that different depths of gray would be shown by exactly

the same proportions of the three colours. This led one to suppose that there was a possibility of getting what might be taken as natural standard mints of tone in the different standard colours in place of the purely arbitrary units at present employed. Referring to Dr. Wright's remarks, he believed it had been mentioned that at present the scales of colours were essentially arbitrary ones. One standard—a pale colour—was taken as a unit in each tint, and the other shades were built up from that by actual trial with the glasses. So far as his own experience had gone he had found the tintometer capable of doing very good service in dealing with both liquids and solids.

Mr. J. J. EASTICK said that he had had one of Mr. Lovibond's instruments in use for the last three years, and had found it simply invaluable. He had, however, experienced one or two difficulties. One was, that some of the colours of the solutions which he tested were brighter and nearer the primary colours than the glasses themselves. Another difficulty—or rather he might say a warning—was that if an observer was looking through an inch of colour in certain liquids, and the colour was, for example, 20, if he then looked through two inches of the same liquid the tint would not be 40, as might be expected. He did not know whether that was the case with all colours, but it certainly was so with several. He had heard with great pleasure the hint thrown out by Mr. Boverton Redwood as to the possibility of overcoming the difficulties of artificial light. Even if the promised light was not so perfect as the reflection from a white cloud, it would still be a boon if it was an improvement upon the present means of carrying on operations during a fog or night.

Dr. MUNRO desired to add a few words as to the use of the tintometer for measuring the colour of water, as he thought it likely to be especially useful to chemists in that direction. In Table 6 he had given, as an illustration, some measurements of a number of waters from one neighbourhood—all within half a mile of a common centre. It would be seen from the figures in the last column that these waters ranged from seven-tenths of a degree of colour in a 2 ft. tube to 53 degrees, which was a most extraordinary variation. He had found the instrument very useful in following certain changes in the Lisdoonvarna sulphur spas. The twin sulphur spas, as shown in the table, always had the same composition; but near it was the Gowlaun spa, from the same formation, which was subject to extraordinary variations in strength. It was to be noted that there was a certain variation in colour also; and so there was probably some connexion between the two things. That enabled them to form some idea of what went on under the ground, for the variation in strength was perhaps due to the percolation of water; and they could in that case ascertain by the variation in colour what particular water was getting in. He had had an opportunity of seeing Mr. Lovibond's neutral gray by daylight, and as far as he could judge it was free from any positive tint.

Mr. LOVIBOND, in reply, said that in reference to Mr. Boverton Redwood's remarks as to the bad quality of London light, it had been found a great difficulty at first, as the small surfaces commanded by the two apertures did not admit sufficient light to illuminate the object. But he had recently overcome it to a great extent by including a reflector at a low angle, so as to collect the light from a large surface and throw it into the comparatively small space. An illustration of this would be seen upon the table in the form which his assistants called the Eiffel tower. He had not as yet given much attention to the use of the instrument with artificial light, but he had no hesitation in saying that, given the said light had permanent characteristics, there would be no difficulty in establishing its relative value compared with daylight, and thus making it available with a certain constant correction. With reference to Mr. Thorp's doubt as to the exact representation of tint—that was the strong point of the instrument, and half an hour's work by daylight would completely satisfy the most sceptical on that point. As to the purity of the colours, he was very much at fault. He had only a certain material to deal with, and he made the most he could of it. He had a blue, for instance—he

called it a blue, but it was really a purple; for it was a cobalt put on white glass. To seek for absolute purity of colour in glass, taking the spectrum colours as his standard, would be futile. But for ordinary colour measurement, all that was needed was to employ so much more or less red, blue, or yellow to compensate for the departure from purity in the standards. This was no real detriment to the value of the instrument for measuring commercial colours; but it would be fatal to the measurement of pure colours *directly*—though they could be measured *indirectly* by toning the pure colours down by a series of neutral grays. As to the permanence of the colours, he had the assurance of the makers, the red being oxide of gold, the yellow silver, and the blue cobalt. Under these circumstances he could not guarantee their permanence; but if any chemist would establish the value of a unit for any coloured chemical compound, he would have the power of testing for himself its permanence. As to the value of a degree on his scale of tints, that was purely arbitrary, and it was fixed so that the difference of a degree up to 30 might be just perceptible. It started at 1; then the 2 was equal to two 1's. If he had to deal with two glasses against one, he added a white glass to the one, so as to equalise the number of surfaces on each side. As to the spectrum value of the colours, he had already said that the two were not comparable. If he had to compare his colours with the spectrum colours, he should tone the latter down to his colours and get the indices on the spectrum side. He said this to show the elasticity of the instrument to meet any question asked of it. The accuracy of the scale of colours was in the hands of the chemist; and if anyone found a scale inexact he hoped they would bring it to his notice. No real difficulty existed in grading the colours beyond the necessary labour, which was excessively trying. As to reproducing the scales, he had deposited standards at the colleges of Liverpool, Leeds, and Bradford, on the condition that anyone using the tintometer should be at liberty to take his glasses to the college and test them with the standards. With reference to Mr. Friese-Greene's remarks as to the interference of complementary colour sensations, that was a serious difficulty in judging the value of any one colour; but when judging the difference between two colours placed side by side, as in the tintometer, it counted for nothing. In matching two colours in the instrument with one eye, any interference equally affected both sides, and whatever colour impressions might be conveyed to the eye by the interference, the measuring glasses required to make a match were the same. That was proved by the diagrams which dealt with the judging of certain colours under different conditions; in which it would be seen that although the lights varied, the same results were obtained by a considerable number of persons, thus showing that the question of outside influences (arising from adjacent colours) did not apply. The observer was simply judging of two things before him; and if one observer called it a green, while another said it was a red, that made no difference when the two sides were equal. The glasses were the indices of the difference; and as the glasses were always the same, they reduced these hitherto unmeasurable differences to a matter of common understanding. He had not as yet met with any difficulty as to the reproduction of his scale. If difficulties did arise, all he could say was that they would have to be overcome. Solutions brighter than the glasses were at one time a source of difficulty which was only overcome by the discovery of the theory of the neutral grays. If the observer had a solution brighter than the glass, he would first add an equal number of glasses, and if that were not sufficient, it was evident that he was dealing with a purer colour than the glasses themselves. He would then add glasses to the pure side and bring that down to the impure. In either case the glasses required would be the indices of the difference.

### WIBORGH'S METHOD FOR THE ANALYSIS OF SULPHUR IN IRON AND STEEL.

J. B. COHEN, PH.D.

THIS method, which has recently been published in detail in Professor Ledebur's new volume on iron and steel analysis (*Leitfaden für Eisenhütten-Laboratorien*: Vieweg und Sohn), is described as rapid and accurate. The apparatus is shown in the figure.

It consists of a wide-necked flask, *a*, of 250–300 cc. capacity, to which is fitted a double-bored cork. Through one hole passes a tap-funnel, *b*, which terminates just below the cork, and through the other a cylindrical glass tube, *c*, about 21 cm. long, open at both ends. The upper end is about 6 cm. in diameter and the lower end drawn out so as to pass through the second hole in the cork. The amount of sulphur is determined by the depth of the yellow stain produced by  $H_2S$  on the surface of a piece of calico previously soaked in a 5 per cent. cadmium acetate solution and dried, the calico being stretched across the wide open end of the cylindrical tube.

The calico may be stretched by means of two stout india-rubber rings  $\frac{1}{2}$  inch in width, which fit tightly round the upper part of the wide tube. One ring is allowed to project above the tube so as to form a horizontal edge, and over

this the calico is stretched by means of the second ring. Ledebur employs a wooden ring and two clamps, but the above method answers perfectly well.

The flask is first half filled with water and boiled on a sand-bath to expel air, the sample of iron or steel, .1 to .8 gm., according to the amount of sulphur, is quickly introduced, and the water again boiled for a few minutes; dilute sulphuric acid (1:5) is introduced from the tap-funnel gradually until the iron is dissolved without interrupting the heating.

Sulphuretted hydrogen is evolved and the calico is stained. To obtain an even stain it is necessary that the cylindrical tube should have a vertical position. When the iron is completely dissolved, the boiling is continued for 8 to 10 minutes. The calico is now removed, well rinsed, and dried, and the stain compared with a set of standard colours. The set of standards (six shades are sufficient) is prepared by taking a sample of iron with a known quantity of sulphur and obtaining various shades with different weights of the sample by the method described above. These should be mounted on white cardboard and kept for comparison. Having made an analysis and fixed upon the standard shade which comes nearest to that of the sample, the weight of sulphur is determined by the following formula:—

If *w* is the weight of the standard sample corresponding to the standard shade containing *s* of sulphur, and *w*<sub>1</sub> is the weight of the sample taken, then the weight of sulphur *s*<sub>1</sub> in the sample is  $s_1 = \frac{w s}{w_1}$ .

The same standard shade can therefore be used for a variety of samples when different weights are employed.

### A PRODUCT OF THE DISTILLATION OF ROSIN.

BY F. BROWN-SWORD, B.S.C., AND J. B. COHEN, PH.D.

A SAMPLE of the aqueous distillate from a rosin still was sent us for examination. As we have been unable to find any mention of the constituents of this distillate, we thought a short notice of our results would be of interest to the Society.

The proportion of this aqueous distillate amounts to about one-third per cent. of the charge. It has a strongly acid reaction and smells of rosin oil, of which there is always a small quantity floating in oily drops on the surface. The acid, which was found to be acetic acid, was present partly as free acid, partly as ferrous salt. The acid, which in one case was collected in wooden barrels, had evidently attacked the iron condenser or pipe leading from the still. We received samples of two distillations. The quantity of acid was determined as follows: To 1,000 cc. of the distillate ammonia was added until alkaline and  $H_2S$  passed into the solution to precipitate the iron. The filtrate was concentrated and boiled with excess of baryta and the excess precipitated with  $CO_2$ . The solution was filtered and evaporated to dryness. In the litre 23.8 grms. of barium acetate were found. In a second quantity, 500 cc. yielded 12 grms. barium acetate. This is equivalent to 12 grms. acetic acid in the litre, or rather more than 1 per cent.

In the second distillate the barium salt was obtained as before, and converted into the sodium salt, which was fused and weighed. One litre gave 170 grms. of fused salt equivalent to 120 grms. of acetic acid, or about 12 per cent. The sodium salt was heated with concentrated sulphuric acid, and the acetic acid which distilled was again distilled over  $P_2O_5$ , when the product froze on cooling to 0°. The lead salt prepared from this acid gave the following result on analysis. .5035 gm. gave .403  $PbSO_4$ .

Calculated.	Found.
54.61	54.57 per cent.

## A COMPARISON OF THE METHODS IN USE FOR ESTIMATING ORGANIC NITROGEN.

BY R. W. ODDY, A.I.C., AND J. B. COHEN, PH.D.

THERE is no analytical process which has had more demands made upon it in recent years than a rapid and reliable method for estimating organic nitrogen. The new process of Kjeldahl appears to have supplied these requirements. That of Wanklyn is obviously inadequate, especially as it has been shown that ammonia is decomposed by alkaline permanganate on long boiling. Dumas' method has stood the test of time.

It appeared to us interesting to make a comparison of these three methods, and to determine how nearly they agreed.

Colourless isinglass was selected as a typical albuminoid substance. It was powdered and dried and analysed by the three processes.

The analyses by Dumas' method, which needs no description, gave the following results:—

No. of Analysis.	Weight taken.	Ce. of Nitrogen.	Temp.	Pressure.	Per Cent. of N.
1	Grm. '1292	17.2	20	Mm. 746.5	15.28
2	'1595	20.6	19.5	760	15.2
3	'201	27.6	20	755	15.93
4	'1771	23.3	21	755	15.22
5	'1335	17.8	17	760.1	15.74

As this method always gives too high a result due to the difficulty of completely expelling all air from the tube, we may take 15.2 per cent. as a close approximation to the truth.

A portion of the same sample of isinglass was dissolved in water, and the amount of the albuminoid ammonia determined exactly as described by Wanklyn in his volume on Water Analysis. It should be mentioned that a *very small* quantity of the sample remained undissolved and in suspension, and the analysis is to that extent unreliable. On the other hand we are not limited in Wanklyn's process to dissolved albuminoids, and, moreover, the result agrees exactly with Wanklyn's analyses of the same substance (*vide* p. 163, sixth edition, p. 183, seventh edition).

We found 12.75 per cent. of ammonia, Wanklyn 12.7 per cent. of ammonia, equivalent to 10.5 per cent. of nitrogen.

As might have been anticipated, the percentage is much too low, being nearly two-thirds of the actual amount.

The method of Kjeldahl was carried out as described in Dittmar's book on Quantitative Analysis, p. 83. The sulphuric acid used was distilled, as it was found that the commercial acid contained nitrites and nitrates. In distilling the sulphuric, the first portion passing over was rejected.

The following are the results:—

No.	Per Cent. N found.	
1	13.50	With pure sulphuric acid.
2	13.50	
3	13.59	
4	14.12	With a sample of commercial H <sub>2</sub> SO <sub>4</sub> .
5	14.25	
6	14.14	
7	15.8	With another sample of commercial H <sub>2</sub> SO <sub>4</sub> .
8	15.2	

With the exception of No. 2, in which litmus was used as an indicator, the titration was done with methyl orange.

Taking 13.5 per cent. as nearest to the truth, we see that it is very much too low in comparison with Dumas' process.

Although the majority of observers have obtained satisfactory results by Kjeldahl's process, and it is undoubtedly to be recommended in the case of the more readily decomposed organic compounds, as we have proved in the case of acetanilide, we have no doubt that in the case of the less easily decomposed bodies the results have a tendency to be much too low.

## THE STABILITY OF PERMANGANATE SOLUTIONS.

BY R. W. ODDY, A.I.C., AND J. B. COHEN, PH.D.

It is known that solutions of permanganate of potassium lose in strength on keeping, but the exact amount of this loss has never been ascertained. The object of the present paper has been to determine this amount.

A solution of permanganate was prepared in the usual way by dissolving about 5 grms. of the crystallised salt in about a litre of distilled water, which was then boiled for two to three hours, and, when cold, diluted to one litre. The strength of this solution was determined by titration with iron wire dissolved in sulphuric acid, and also by solution of ferrous ammonium sulphate of ascertained purity. The results of the two determinations agreed exactly. The solution of the permanganate was now divided between two well-stoppered bottles, one of which was kept in the dark, the other exposed to the light during a period of about four months, and the strength ascertained at intervals.

The testing of the permanganate was carried out in the same manner as already described. On each occasion fresh solutions of the same sample of iron wire in sulphuric acid and of ferrous ammonium sulphate were prepared.

The results show that light has no influence in the change, but that regular though slight decrease in strength occurs, as shown by the tabulated results.

Strength of 1 cc. KMnO <sub>4</sub> in Grms. of Fe.			Strength of 1 cc. KMnO <sub>4</sub> in Grms. of Fe.		
Date.	Exposed to Light.		Date.	Kept in Dark.	
	Iron Wire.	Double Salt.		Iron Wire.	Double Salt.
1887. Nov. 14	'00968	..	1887. Nov. 14	'00968	..
Dec. 1	'00964	'00963	Dec. 1	'00964	'00963
" 10	'00960	'00960	" 10	'00963	'00960
" 20	'00961	'00959	" 20	'00959	'00962
1888. Jan. 10	'00955	'00959	1888. Jan. 10	'00959	'00959
March 8	'00940	'00941	March 8	'00948	'00952

By the method of testing, a single drop of permanganate might produce an experimental error equivalent to about  $\frac{1}{2}$  per cent. of iron in each cc.

The table, therefore, is only reliable to .5 in the fifth decimal place. There is, however, a difference during the four months of a full 2 per cent., allowing for experimental error, though the probability is it amounts to 3 per cent.

The decrease is apparently regular. During the first two months, November 14—January 10, there is a loss equivalent to 1 per cent. of iron, and during the last two months nearly the same. This loss translated into percentages will of course vary with the amount of iron in the sample. In the case of a sample with, say, 25 per cent. of iron, this amounts to  $\frac{1}{2}$  to  $\frac{3}{4}$  per cent.

It therefore appears that permanganate solutions which have been previously well boiled should be tested once a fortnight to ascertain the amount of change, and that the amount of change during this period will not exceed that of experimental error and may be neglected.

MR. J. CARTER BELL said that he had kept solutions of permanganate for many months, and had found the change to be very slight. Nearly 30 years ago Dr. Percy had experimented upon this very subject, and in March 1862 he prepared a large quantity of permanganate, and on that date he obtained as a mean of four experiments a standard of 9.854 (1,000 grains of solution = 9.854 grains Fe).

The solution was again standardised in March 1863, and the mean of two experiments gave a standard of 9.797 (10,000 grains of solution = 9.797 grains Fe), or an alteration in 12 months of only .057 grain.

There was no necessity to boil the solution of permanganate if pure distilled water were used.

## THE RATE OF DISTILLATION OF ACETIC ACID.

BY J. A. WILSON.

THE results of the experiments contained in this paper were obtained some short time ago, in an attempt to apply the principle of researches made by M. Duclaux, on the rate of distillation of various fatty acids, to the valuation of commercial acetates. Duclaux found on distilling solution containing various fatty acids, that each acid possessed a rate of vaporisation peculiar to itself, moreover, the least volatile acids, distilled in the portions of distillate, coming first, whilst acetic and formic acid behave in the opposite manner. In the case of acetic acid, Duclaux found that when 110 cc. of a liquid containing acetic acid were distilled in a retort of 250 to 300 cc., that by the time 100 cc. of the liquid had passed over or 10/11, it contained 79.8 per cent. of the total quantity present. Formic acid does not distil so easily, whilst on the other hand propionic acid is more volatile, and butyric acid again more than the latter. When two or more acids are present in a liquid, each maintains its own special characteristic rate of distillation. Tables showing these special characteristics may be found in most of the works on organic analysis (Allen's Commercial Organic Analysis, vol. I, p. 408; Wynter Blyth, Food, p. 488), and I may say that I have not been able to find any other researches on the same subject other than those under discussion. The experiments made were mostly from a technical point of view, and, as stated above, mainly with the intention of applying the principle to the commercial assay of acetates, acetic acid, and vinegars. In most of the text-books on analysis tables are given showing the rate at which each acid distils, but no mention is made of the strengths of the solutions the author experimented with. However, as the process was mainly intended for the detection of volatile acids of wine, we may reasonably consider they would be dilute. In my experiments a 250 cc. retort was employed attached to a condenser 22 in. long and diameter of  $\frac{1}{2}$  in., and the neck of the retort was not surrounded by a dome, or wrapped with flannel, or any other of the devices to confine the heat and thus prevent condensation.

Pure semi-normal alkali was used for the titration, with phenol phthalin as indicator.

In Table 1, 110 cc. of the acid of strength mentioned in column 1 were pipetted into a 250 retort and distilled at the usual rate till 100 cc. had passed into a graduated receiver, the amount of acid in the distillate being then found by heating with slight excess of alkali, cooling, and then adding semi-normal hydric chloride till pink colour discharged. That signified under total was obtained by direct titration.

TABLE 1.

$C_2H_3O_2$ per Cent. Total.	$C_2H_3O_2$ in 10/11 Distillate.	Per Cent. of $C_2H_3O_2$ in 10/11 Distillate of that in Retort.
1.015	0.928	83.15
2.287	1.896	82.90
4.18	3.81	83.52
10.45	9.49	82.56
26.19	23.73	82.37

The above experiments were carried out most carefully, and in duplicate, and I was somewhat disappointed in them. I ought here to mention that there being danger in distilling such as the No. 5 strength of acid, an aliquot portion was taken, so as to bring it approximately to No. 4, and made up to 110 cc. and distilled to 10/11 as before.

Table 2 shows the results obtained from three commercial samples of vinegar, with the difference that the figures under total are obtained by successive distillations with addition of water.

TABLE 2.

Acetic Acid per Cent., Total.	Acetic Acid in 10/11 Distillate.	Per Cent. of Acetic Acid in 10/11 Distillate to that in Retort.
4.406	3.705	82.96
4.530	3.78	83.44
4.75	3.97	83.58

The above samples of vinegars gave precipitates with silver nitrate and barium chloride; on account of the former a little silver sulphate was added. Commercial vinegars as a rule contain from 2.5 to 3.7 per cent. solid matter, but they do not appear to have affected the distillation much.

Table 3 shows the influence of neutral salts, sodic chloride, and sulphate, on the speed of distillation, No. 3 being accounted for on the pressure of approximately 56 per cent. of hydrated water.

TABLE 3.

$C_2H_3O_2$ Per Cent. Total.	Amount of Neutral Salt per 100 cc.	$C_2H_3O_2$ in 10/11 Distillate.	Per Cent. in 10/11 Distillate to that in Retort.
10.26	5 grms. pure NaCl.	10.47	92.77
"	10 " " "	10.92	96.76
"	5 grms. $Na_2SO_4$ 10 aq.	9.75	86.39

The influence of phosphoric acid was the subject of two more experiments, the solution being prepared by dissolving 220 grms. of glacial phosphoric acid in 200 cc. of water. The purity of the acid was proved by treating 20 cc. on the retort and distilling to dryness, no volatile acid being obtainable.

TABLE 4.

100 cc. Acid Solution, 10 cc. Phosphoric Acid, $C_2H_3O_2$ Total.	$C_2H_3O_2$ in 10/11 Distillate.	Per Cent. of $C_2H_3O_2$ in 10/11 to that in Retort.
10.05	9.90	98.51
4.25	4.16	97.88

The experiments I next made with the commercial acetates were conducted in the usual manner, in the same retort, viz., that of 250 cc. capacity, which is considerably larger than that usually employed, which is about from 125 to 170 cc. The same phosphoric acid was employed, and

the quantity of substance taken was arranged so as to give as near as possible the same amount of volatile acid. The standard was that of potassium acetate, which was made by dissolving 2.5 grms. in 250 cc. of water. 100 cc. was then taken by an accurate pipette in the retort, and 10 cc. phosphoric acid added, distilled to 10/11, and the quantity of acid in the distillate found by titration. Water was added to the retort after cooling, and distilled to about 5 cc. successively till any acid came over. Results in Table 5:—

TABLE 5.

Commercial Salt.	C <sub>2</sub> H <sub>3</sub> O <sub>2</sub> Per Cent. Total.	C <sub>2</sub> H <sub>3</sub> O <sub>2</sub> in 10/11 Distillate.	Per Cent. of Total in 10/11 Distillate.
Acetate potassium .....	60.22	57.00	94.65
Acetate soda.....	44.23	43.22	97.74
„ chrome (liquid) ..	10.605	10.20	96.18
„ „ (solid) ...	50.61	48.50	95.83
„ „ (2 spec.) .	48.66	46.30	95.15
„ copper (pure)....	60.36	59.70	98.90
Acetate lime liquid 24° T...	13.24	12.68	95.77
„ „ „ „	12.88	12.38	96.11
Sulpho acetate alumina: Tin red liquid 16° T...	7.32	6.97	95.22
„ „ „ „	6.79	6.48	95.43
Sulpho acetate alumina: Scarlet liquor 16° T...	5.90	5.60	94.91

The lowest of the above results is 94.61 in the case of acetate of potassium, whilst the highest, that of cupric acetate, is 98.9; the mean result is 95.99 per cent. I have constructed Table 6 on this mean result, and it shows the results in conjunction with those actually obtained.

TABLE 6.

Name of Salt.	C <sub>2</sub> H <sub>3</sub> O <sub>2</sub> from 95.99 per Cent. Factor.	C <sub>2</sub> H <sub>3</sub> O <sub>2</sub> per Cent. Actual from Column 2, Table 5.	Error.
Acetate potassium.....	59.38	60.22	+ 0.84
„ soda.....	45.03	44.23	+ 0.80
„ chrome .....	10.62	10.605	+ 0.015
„ „ (solid)	50.52	50.61	- 0.09
„ „ „	48.23	48.66	- 0.43
„ copper.....	62.19	60.36	+ 1.83
„ lime, 24° T....	13.21	13.24	- 0.03
„ „ „	12.59	12.88	+ 0.01
Sulpho acetate alumina: Tin red liquor.....	7.26	7.32	..
„ „ 2.....	6.75	6.79	- 0.04
Sulpho acetate alumina: Tin red liquor.....	5.83	5.90	- 0.07

The results above are seriously in error in two or three cases, and whether the mean factor 95.99 will be used, each one will decide himself. In the majority of cases the results come very near those calculated.

## ON A METHOD FOR DETERMINING ALKALIS IN PRESENCE OF SULPHITES.

BY JAS. GRANT AND J. B. COHEN, PH.D.

It is impossible to estimate the alkalis in presence of sulphites by ordinary titration with acid, as a certain quantity of the acid is taken up by the sulphite, SO<sub>2</sub> being evolved. Moreover, oxidising agents, such as bromine or nitric acid, to convert sulphite to sulphate, cannot, for obvious reasons, be employed.

Hydrogen peroxide, however, answers the purpose perfectly well. It has no action on the alkalis, and completely oxidises sulphites to sulphates. The method then is to add the requisite quantity of the peroxide, boil up, cool, and titrate the alkalis with acid in the usual way, using methyl orange, which is not affected by the peroxide, as indicator. Since beginning this research we have found that this method of estimation is in use in some alkali works, but believe it has never yet been published.

The effect of hydrogen peroxide on various indicators, as methyl orange, litmus, &c., was investigated, and we found that in the cold neither of these two indicators is attacked, but on prolonged boiling both are decolourised.

Secondly, experiments were made to ascertain whether the sulphite was completely oxidised. A solution of alkaline sulphite was boiled up with the requisite quantity of hydrogen peroxide and poured both hot and cold into a mixture of iodine and starch, but in neither case was the faint blue colour in the slightest degree discharged, showing the absence of sulphur dioxide.

The next point to decide was, whether carbonate or caustic are affected by the hydrogen peroxide. Different weighed samples were dissolved in water, H<sub>2</sub>O<sub>2</sub> added, and the amount of alkali determined. The results were compared with those obtained by titrating a known quantity of the same sample, but without the addition of H<sub>2</sub>O<sub>2</sub>, and proved that peroxide does not affect the estimation of carbonate or caustic.

Lastly, we endeavoured to fix, if possible, the quantity of hydrogen peroxide required to convert the whole of the sulphite into sulphate.

The method of analysis adopted is as follows:—A measured volume of hydrogen peroxide is run into a beaker together with three or four drops of methyl orange. As H<sub>2</sub>O<sub>2</sub> is always slightly acid, a small quantity of a very dilute solution ( $\frac{1}{100}$ ) of NaOH is added by means of a 1 cc. pipette till the neutral point is reached. Next the required quantity of alkaline sulphite solution is added, and boiled up at once, but gently. During the latter part of the boiling the methyl orange is bleached. The solution is cooled under the tap, a few more drops of methyl orange added, and the solution is titrated with normal hydrochloric acid solution. Both methyl orange and litmus give the same results, but the former shows the neutral point more distinctly.

The following table gives the results of several analyses:—

Solution I. consisted of 3 grms. of sodium sulphite and 7 grms. of sodium carbonate dissolved in 500 cc. of water, equivalent to .014 gm. of Na<sub>2</sub>CO<sub>3</sub> in each cc.

Solution II. contained 9.5 grms. of sodium carbonate and 0.5 gm. of sodium sulphite dissolved in 500 cc. of water, equivalent to .019 gm. of Na<sub>2</sub>CO<sub>3</sub> in each cc.

Solution III. contained 9.5 grms. of sodium sulphite and 0.5 gm. of sodium carbonate dissolved in 500 cc. of water, equivalent to .001 gm. of Na<sub>2</sub>CO<sub>3</sub> in each cc.

No. of Experi- ment.	H <sub>2</sub> O <sub>2</sub> taken.	10 cc. of Solution contained Na <sub>2</sub> CO <sub>3</sub> .	Na <sub>2</sub> CO <sub>3</sub> found.	
			After standing Half an Hour.	When boiled at once.
I. a.	Cc. 6.0	Grm. 0.14	Grm. 0.0982	Grm. 0.1033
I. b.	9.5	0.14	0.1409	0.1409
I. c.	10.0	0.14	0.1394	0.1370
I. d.	16.0	0.14	0.1405	0.1420

No. of Experiment.	$H_2O_2$ taken.	10 cc. of Solution contained $Na_2CO_3$ .	$Na_2CO_3$ found.	
			After standing Half an Hour.	When boiled at once.
I. a.	5.0	0.19	0.1893	0.1907
I. b.	10.0	0.19	0.1893	0.1900
I. c.	10.0	0.38	0.3706	0.3796
III. a.	10.0	0.01	0.01326	0.01319
III. b.	10.0	0.01	0.01326	0.01326
III. c.	15.0	0.01	0.01172	0.01195
III. d.	20.0	0.01	0.00989	0.01023

From the foregoing experiments it will be seen that—

1st. The quantity of ordinary 10 per cent.  $H_2O_2$  required depends on the percentage of sulphite present in the alkaline sulphite solution. The "caustic salts" of commerce contain about 50 per cent. of sulphite, hence it is sufficient to take 10 cc. of commercial hydrogen peroxide for every .1 gm. of salts solution, although this gives twice the theoretical quantity of oxygen required to oxidise the sulphite to sulphate. For salts containing above 50 per cent. of sulphite it is better to take double the volume of hydrogen peroxide.

2nd. It is unnecessary to let the mixture of alkaline sulphite solution and hydrogen peroxide stand half an hour before boiling up, seeing that the increase in quantity of acid required for neutralisation is almost inappreciable.

## DISCUSSION ON MR. STEAD'S PAPER ON THE DETERMINATION OF ALUMINIUM IN IRON AND STEEL. (VOL. VIII., p. 965.)

MR. STEAD said that the method described was applicable in all cases where chromium was absent. If that element was present it would be detected (after dissolving up the sodium hydrate fusion) by the yellow colour of the chromate which would in all probability be produced. In such a case the

yellow solution must be well boiled with a few drops of sulphide of sodium or other alkaline sulphide, by which treatment the chromate is reduced, and an insoluble chromium compound produced. From this point the process may be followed as described in the paper.

Mr. THOS. CROSBY, Warrington, analyst at a works where aluminium steel had been tested, had informed him (Mr. Stead) that he had tried the method and had obtained satisfactory results.

MR. LAIDLER suggested that if the process were carried out so as to get the mixed oxides of aluminium and chromium precipitated and weighed, then the chromium might be oxidised and determined by a colorimetric process, which would be sufficiently accurate, considering the small quantities that had to be dealt with.

MR. JOHN PATTINSON stated that he had lately had to examine samples of German silver for aluminium. He was sure that without the method of Mr. Stead he would have been unable to detect any, but with it he had determined in three cases .02, .02, .03 per cent. of aluminium.

MR. RIDSDALE sent the following communication on the subject:—

A few months ago, feeling that a thoroughly good method for estimating aluminium in iron and steel was very much needed, I decided to investigate the matter, and though I have not had time to go into it as far as I had originally intended, I may perhaps be permitted to give a few results for what they are worth.

My first wish was to obtain figures showing clearly the value, or rather the absence of value, of three or four existing methods for separation of  $Al_2O_3$  from  $Fe_2O_3$ , &c.

The amount of Al present in a sample of pure ammonia alum was accurately determined, and this was added in such quantities to solutions of various weights of steel drillings as to give the equivalent of definite percentages of Al.

*First Method tried.*—Precipitates of  $Fe_2O_3$  and  $Al_2O_3$ , as obtained with ammonia and ammonium acetate from HCl solutions oxidised with  $HNO_3$ , dissolved in HCl and titrated with  $K_2Cr_2O_7$  (standard), Al being estimated by difference.

	Per Cent.	Error Per Cent.
Percentage of Al which should have been found	1.57	
Shown by this method	{ 2.49 2.15 2.26	{ .99 .63 .76

Manifestly such a method would be utterly inapplicable for lower percentages.

*Second Method tried.*—Fusion of the above precipitate with "pure"  $KHO$  or  $NaHO$  (in all cases a blank being done) and precipitating, after acidifying with HCl, by  $NH_3$  and  $NH_4C_2H_3O_2$ .

	Per Cent.	Error Per Cent.
Percentage of Al which should have been found	.1	
Shown by this method	{ .105 .16 .18 .05	{ .005 .06 .08 .05

also—

	Per Cent.	Error Per Cent.
Percentage of Al which should have been found	1.50	
Shown by this method	{ .90 1.18 .78	{ .60 .82 .72

The barium hydrate method I have tried on former occasions and failed to get reliable results, but had not tried it with this set of experiments.

At this juncture Mr. Stead told me of his method, and I at once tried it on steels with various quantities of Al added:—

	I.	II.	III.
	Per Cent.	Per Cent.	Per Cent.
Percentage of Al should be	.05	.25	.50
Actually found, Stead's method	{ .044 .064	.22	.495
Error	.005 to .014	.03	.005

From the above results I feel sure that with a little practice almost absolutely correct results can be obtained, and at any rate incomparably better than the other methods cited, which though they answer fairly well when the amount of iron present is relatively small, are worthless when the amount of iron is from 100 to 1,000 times as great as the Al present.

I should like to point out that I think it a distinct advantage to precipitate the Al as phosphate, because some of the P present in steel and iron is sure to be found in any  $Al_2O_3$  precipitate obtained, and the precipitating of the whole of the Al as phosphate therefore simplifies matters greatly.

#### DISCUSSION ON DR. LUNGE'S PAPER ON THE DETERMINATION OF SULPHUR IN PYRITES. (VOL. VIII., p. 966.)

MR. STEAD suggested that the filtration and washing in Dr. Lunge's method might be avoided if the precipitation by ammonia were done in a measuring flask, the liquid made up to a definite volume, and an aliquot portion of the clear liquid, after settling, used for precipitation by barium chloride. If allowance were made for the volume of the precipitate this might be a perfectly accurate method.

MR. WARNE thought that any of the ordinary methods gave accurate results if performed with sufficient care. He had had considerable experience both with the ordinary method of oxidation by nitric acid, solution in hydrochloric acid, and direct precipitation in the acid solution, and also with Teschemacher and Smith's volumetric method; and he had found that these, carefully carried out, gave results concordant with each other and with those got by other methods.

MR. LAYDLER had also had considerable experience with Teschemacher and Smith's method, and found it gave results agreeing with those got both by the fusion methods and by Dr. Lunge's method. His experience of the fusion method was that it very rapidly destroyed the platinum crucibles used.

MR. JOHN PATTINSON had had tests made on the same sample of pyrites to compare the methods of Teschemacher and Smith, Fresenius, and Lunge. The results were:—

Lunge.	Fresenius.	Teschemacher and Smith.
49.20	49.18	49.25
49.22	49.15	49.30

With a view of testing the absolute accuracy of Lunge's method, he had dissolved and oxidised 5 grains iron wire and added 20 grains sodium sulphate; the mixture was then treated by Lunge's method as though it were the solution of a sample of pyrites. Two determinations yielded sulphur corresponding to 20.05 and 20.00 grains of sodium sulphate respectively, showing the method to be very accurate. In point of convenience there was no comparison between Lunge's method and that of Fresenius, which involved at least two evaporations with hydrochloric acid, a second treatment of the iron oxide with caustic soda, and a passage of carbonic acid gas through the solution to get rid of any lead.

#### ON THE GAS-VOLUMETRIC ANALYSES OF POTASSIUM PERMANGANATE, CHLORIDE OF LIME AND MANGANESE PEROXIDE.

BY G. LUNGE.

SOME years ago a paper by Mr. A. H. Allen drew my attention to a great number of new applications of the apparatus now well known by the name of the "Nitrometer." In a paper published in the "Chemische Industrie" 1885, 161 et seq. (very briefly abstracted in the Journal of the Society of Chemical Industry, 1885, 495), I described the manifold uses to which the nitrometer can be put as an apparatus for gas analysis proper, as an absorptiometer, and especially for gas-volumetric analyses. To fit it for the last-mentioned object, I added to it a flask, provided with an inner tube fused on to its bottom, and suspended from the side tube of the nitrometer, as shown in Fig. 1, which at the same time exhibits the Greiner and Friedrich's patent tap (a similar one is known as the Geissler-Miescher tap, and is

Fig. 1.

Fig. 2.

Fig. 3.

applied to the nitrometers supplied by the firm of Dr. H. Geissler at Bonn). This shows how any ordinary nitrometer, such as are now found in most chemical laboratories, can be applied to the afore-mentioned uses. Where, however, the methods concerned are to be employed not merely occasionally, but regularly, it will be preferable to get a nitrometer specially adapted to this use, of which Figs. 2 and 3 show various forms. They have no cup at the

top, which is quite unnecessary for this purpose, but merely a short outlet-tube for air. Fig. 2 shows an instrument provided with one of the new patent taps, which are certainly very handy, and cause a much smaller number of spoiled tests than the ordinary three-way tap, as shown in Fig. 3, which at the same time exhibits the form of nitrometer intended for large quantities of gas, the upper part being widened into a bulb, below which the graduation begins with either 60 or 100 cc., ending at 100 or 140 cc., respectively. There are also various shapes of flasks shown in these instruments, but it is unnecessary to say that these, as well as the bulb arrangements, can be applied to any other form of the instrument. The nitrometers used for gas-volumetric analyses are best graduated in such manner that the zero point is about a centimetre below the tap, whilst ordinary nitrometers have their zero point at the tap itself. I will say at once that for all the cases to be mentioned in the following it is quite unnecessary to employ mercury for filling the instruments, since identical results are obtained with ordinary tap water; but it is decidedly advisable to place this instrument, like any ordinary nitrometer or any other apparatus in which gases are to be measured, in a room where there are as few changes of temperature by cold draughts or gas-burners and so forth as possible.

I shall in this place only treat of those of the manifold uses of the nitrometer, in which *hydrogen peroxide* is used as the principal reagent, and although the methods I shall mention have been previously mentioned by me, both in the above quoted paper and *passim* in the *Berliner Berichte*, &c., I shall now, for the first time, give such data as will amount to a conclusive proof of the correctness of the results to be obtained by this analytical method.

I shall commence with one of the most "elegant" of these methods, and at the same time that which possesses the greatest attainable degree of accuracy, namely the *standardising of potassium permanganate without scales, weights, or substances of accurately known composition*. In this case it is necessary to work with *acid* solutions containing a large excess of sulphuric acid. I had frequently employed this method concurrently with the iron method, but in order to make sure of the degree of accuracy obtainable by this method, I caused Dr. Lengfeld to make a number of specially careful estimations, for which all graduated vessels were calibrated and the materials employed were analysed beforehand. Only the hydrogen peroxide, accidentally, was not tested for its strength, but fortunately this is of no moment, as in this case even a large excess of the reagent can be employed without any difference in the results.

The potassium permanganate employed was made from pure crystals, and was as nearly seminormal as possible, i.e., each cc. corresponding to 0.004 gram oxygen. It was standardised: 1st, with iron wire which was found by analysis to contain 99.9 per cent. of metallic iron; 2nd, with crystallised oxalic acid, purified according to Cl. Winkler's prescription and dried up to constant weight in a Victor Meyer's air-bath at 56°; 3rd, with ordinary commercial peroxide of hydrogen. The results were as follows:—

#### A. Standardising with iron wire.

cc.	Gram. Oxygen.
1 permanganate solution yields.....	0.004002
1 " " " .....	0.003998
1 " " " .....	0.003996
Average .....	0.003999

#### B. Standardising with oxalic acid.

cc.	Gram. Oxygen.
1 permanganate yields .....	0.003998
1 " " " .....	0.003995
Average .....	0.003997

#### C. Standardising with hydrogen peroxide in the nitrometer.

(a.) 10 cc. permanganate + 15 cc. dilute sulphuric acid (1:5) and 15 cc.  $\text{H}_2\text{O}_2$ , shaken up, allowed to stand 10 minutes, shaken again and read off after 15 minutes.

Volume of Oxygen.	Temperature.	Barometer.	The same Corrected.	Volume of Gas at 0° and 760 mm.	1 cc. Permanganate yields, Gram. Oxygen.
Cc. 61.6	°C. 12	Mm. 722	Mm. 711	55.13	0.003951
61.4	13	722	709	54.70	0.003920
61.4	13	730	717	55.28	0.003991
60.2	12	729	718	54.47	0.003904
Average .....					0.003911

(b.) Conditions as before, but 30 cc. sulphuric acid used in lieu of 15 cc.

Cc.	°C.	Mm.	Mm.		
62.3	12	721	712	55.92	0.004007
62.5	13	724	711	55.82	0.004000
62.3	12.5	724	712	55.82	0.004000
Average .....					0.004002

If we exclude series C. (a.) in which, as is evident at once from the considerable variation of the results, the proper conditions had not been attained, the quantity of acid not being large enough, we find as averages of the three methods of standardising the same permanganate solution:—

- A. With iron wire 1 cc. = 0.003999 gram oxygen.  
 B.  $\alpha$ -oxalic acid 1 " = 0.003997 " "  
 C. With  $\text{H}_2\text{O}_2$  1 " = 0.004002 " "

Of methods A. and B. the former possesses the greater degree of reliability, since it is extremely difficult to prepare absolutely pure and dry crystallised oxalic acid.

The averages of A. and C. agree better than the single experiments with iron wire do among one another. We cannot but infer that *standardising a solution of potassium permanganate with hydrogen peroxide in the nitrometer, when observing the prescribed precautions, is one of the most accurate known methods for this purpose, and withal possesses the great advantage that it is carried out within an extremely short time, without requiring a fundamental substance of accurately known composition.*

Anybody who has worked in this field will know without special instructions that no gas-analytical operation can yield accurate results unless the graduation of the instruments has been checked, and unless the apparatus is protected against changes of temperature from draughts, gas-burners, and so forth. This of course equally applies to the following methods.

We shall now describe the estimation of *chloride of lime* (bleaching powder or bleach liquor) by means of hydrogen peroxide. The reaction is here—

It is not necessary to know the exact composition of the hydrogen peroxide, but as it is desirable not to employ too large an excess of it in this case, it is best to estimate its percentage by a preliminary test occupying but a few minutes, in which a certain volume of  $\text{H}_2\text{O}_2$  is decomposed by an excess of bleach solution (the inverse of the titration of the latter). This need be done only quite roughly. For the analysis of chloride of lime the hydrogen peroxide must be diluted before use so as not to give out more than 7 cc. of oxygen per cc., and it must be made alkaline by means of caustic soda solution up to the point where a flocculent precipitate appears. The alkaline reaction ought to be quite

distinct, but any *great* excess of alkali should be avoided. It is not necessary to shake much, and the reading ought to be made quickly, say five minutes after mixing the liquids, otherwise the results will be too high owing to the gradual evolution of more oxygen from the alkaline liquid. It might be thought that muddy solutions, such as are regularly employed in testing commercial bleaching powder, would yield less reliable results, the solid matter favouring the evolution of oxygen from  $\text{H}_2\text{O}_2$  otherwise than through the action of  $\text{CaOCl}_2$ ; but this is not so; muddy solutions can be tested by the nitrometer just as well as clear bleach liquors, provided the time of five minutes is not exceeded. As the reaction does not produce a sensible change of temperature, that time will quite suffice, provided that the operator has avoided raising the temperature of the flask in manipulating it, which he can do by handling it always by the neck with his thumb and forefinger only.

It may be as well to give here a general description of the mode of procedure for manipulating gas-volumetric analysis with the nitrometer, common to all analyses according to this method. Fill the nitrometer with water or mercury by raising the level tube till the level of the liquid in the graduated tube is at zero (in the case of instruments bearing the zero-mark a little below the tap, as in Figs. 2 and 3), or at 1.0 cc. (in the case of ordinary nitrometers, beginning their graduation at the tap itself). It is unnecessary to say that in the latter case all readings must be diminished by 1 cc. Close the glass tap. Put the substance to be tested into the outer space of the flask, together with any other reagent apart from the  $\text{H}_2\text{O}_2$  (in the case of bleaching-powder nothing but the bleach liquor, in that of potassium permanganate the 30 cc. of sulphuric acid, &c.). Now put the  $\text{H}_2\text{O}_2$  into the inner tube of the flask, after having, in the case of testing for chlorine, made it alkaline in the previously described way. Put the india-rubber cork, still hanging from the tap, on to the flask, without warming the latter as above described. As this produces a compression of the air within the flask, remove this by taking out the key of the tap in Figs. 1 or 2, or, in Fig. 3, turning it for a moment so as to communicate with the short outlet tube. Now turn the tap back, mix the liquids by inclining the flask, shake up and allow the action to proceed. As the gas passes over into the graduated tube, lower the level tube, so as to produce no undue pressure; at last bring the liquid in both tubes to an exact level and read off.

In our special case all the oxygen of the chloride of lime is given off, together with exactly as much oxygen of the  $\text{H}_2\text{O}_2$ . The total is just equal to the volume of chlorine gas which would be given off by the chloride of lime, and thus immediately represents the French or Gay-Lussac chlorometric degrees, of course after reducing the volume to  $0^\circ$  and 760 mm. pressure. (The reading of the barometer must be corrected by deducting the tension of aqueous vapour for the temperature observed as well as the expansion of mercury, according to the tables found everywhere). These reductions can be easily performed by the tables contained in the "Alkali-Makers' Pocket-book" (pp. 28 to 39), which I had calculated a number of years ago, just in order to facilitate the use of the nitrometer. Other tables are found in the same place, pp. 40 to 42, and in Winkler-Lunge's Handbook of Technical Gas Analyses, p. 114 et seq. All tables can be dispensed with, as well as the reading of the thermometer and barometer, when using the reduction instrument, invented at the same time by Cl. Winkler and myself, of which I have recently published a more convenient modification (Chemiker Zeitung, 1888, 821), an instrument no doubt procurable by every English dealer in chemical apparatus.

In order to find the percentage of available chlorine by weight, that is, the English chlorometrical degrees, it should be borne in mind that every cc. of gas evolved, reduced to  $0^\circ$  and 760 mm., represents 0.003167 grm. of chlorine. Hence, if the quantity of bleach employed is = 1 grm. (for instance, by dissolving 20 grms. in 500 cc. of water, and employing 25 cc. of the solution for each test), each cc. of gas is = 0.3167 per cent. of available chlorine in the bleach. This involves the use of a bulb nitrometer holding 140 cc. If only a 50 cc. instrument is at hand, it will be necessary to take, say, 5 cc. of the first-mentioned bleach solution, in

which case every cc. of gas represents  $5 \times 0.3167 = 1.58$  per cent. of chlorine. The most convenient way is to dissolve 7.917 grms. of bleach in 250 cc. of water, and employing 10 cc. of the solution for each test, when each cc. of oxygen evolved will directly indicate 1 per cent. of available chlorine, and a 50 cc. nitrometer should be used.

The following comparative tests were made by two of my students, Messieurs Schubert and Obregia, on the one hand with the nitrometer, on the other hand with Penot's method (sodium arsenite and potassium iodide as indicator). The work was done as carefully as possible, all instruments being again controlled for the accuracy of their graduation. The results were as follows, all calculated as per cent. available chlorine in 100 solid bleaching powder.

A. Muddy bleach solution. Hydrogen peroxide distinctly alkaline.

(OBREGIA.)

Nitrometer.	Penot.
31.77	31.50
31.73	31.46
31.70	..
31.67	..
Average 31.72	31.48

B. Muddy solution.  $\text{H}_2\text{O}_2$  more strongly alkaline.

(OBREGIA.)

Nitrometer.	Penot.
31.65	31.50
31.67	31.46
Average 31.66	31.48

C. Muddy solution. Hydrogen peroxide made alkaline to the point where a flocculent precipitate begins to form (same treatment as in all following series).

(SCHUBERT.)

Nitrometer.	Penot.
36.67	36.60
36.63	36.72
Average 36.65	36.70

D. Muddy solution. 4 cc. hydrogen peroxide containing 5.4 per cent.  $\text{H}_2\text{O}_2$ .

(SCHUBERT.)

Nitrometer.	Penot.
29.89	29.60
29.87	
29.79	
29.73	
Average 29.82	

E. Muddy solution. 5 cc. of the same  $\text{H}_2\text{O}_2$  diluted with 10 cc. water.

(SCHUBERT.)

Nitrometer.	Penot.
30.45	30.27
30.38	
30.42	
30.46	
Average 30.43	

F. Filtered, clear solution. 5 cc.  $\text{H}_2\text{O}_2$  + 10 cc. water:—

Nitrometer.	Penot.
30.23	30.04
30.19	
Average 30.21	

G. Filtered solution. 7 cc. of hydrogen peroxide (rather weaker) + 10 cc. water (= 1.3 per cent.  $\text{H}_2\text{O}_2$ ).

## (SCHUBERT.)

Nitrometer.	Penot.
29.87	29.60
29.75	
29.79	
29.78	
Average 29.78	

II. Same solution. 10 cc. of same  $\text{H}_2\text{O}_2$  + 15 water (= 1.44 per cent.  $\text{H}_2\text{O}_2$ ).

## (SCHUBERT.)

Nitrometer.	Penot.
29.74	29.60
29.70	
Average 29.72	

I. Influence of different liquids employed for filling the nitrometer, under the same conditions in every other respect.

## (SCHUBERT.)

Mercury.	Water.
29.64	29.64
29.64	29.63
Average 29.65	29.65

N.B.—A large series of similar comparative tests, carried out by other students, yielded precisely the same results, viz., that the estimations are just as accurate when water is used in the nitrometer as when using mercury. The meniscus must, of course, be treated in both cases equally for zero and for the final reading.

The above-quoted results show that the nitrometric method yields quite as concordant results in the testing of bleach as Penot's method, and that both methods are very nearly identical in their results. Still, there is always a little more found in the nitrometric method; but when working in the proper way, with no very large excess of  $\text{H}_2\text{O}_2$  (Series II. proves that a moderate excess does no harm), and not allowing to stand too long, the deviation does not exceed 0.2 per cent., and this amount might be deducted as a constant from the nitrometric results, to bring them into entire concordance with those obtained by Penot's method.

We may, then, conclude that the nitrometer offers an excellent method for checking the results obtained by Penot's method, and for avoiding any errors creeping in by wrong standard solutions. The fact that no standard solution whatever is required in my process makes it specially recommendable for the users of chloride of lime—for instance, bleachers, paper-makers, manufacturers of chloroform—as needs no further explanation.

The analysis of *manganese ore*, or of *Weldon mud*, by means of the nitrometer, offers the great advantage of a saving of time as well as of all standard solutions. In this case the reaction must take place in an *acid* medium. The finely-powdered ores or the Weldon mud are put into the outside space of the flask, and are first treated with dilute sulphuric acid, in order to decompose any carbonates present. Then the hydrogen peroxide is put into the inner tube, the flask is attached to the nitrometer, the liquids are mixed and shaken up, till the colour of the residue shows that the decomposition is complete. With Weldon mud it is instantaneous.

The reaction is—

Half the oxygen evolved comes from the manganese peroxide, hence each cc. of gas corresponds to 0.003897 grm. of  $\text{MnO}_2$ . If 0.3897 grm. manganese ore have been weighed out for each test, the number of cc. of gas evolved indicates immediately the percentage of  $\text{MnO}_2$  in the ore. Comparative tests between this and the ordinary iron-sulphate process, made by Mr. Biedermann, showed—

Nitrometer.	Iron Process.
62.2	62.1 per cent.
62.4	62.3 "
Average 62.3	62.2 "

The following tests were made by Mr. Ruhoff with a very inferior description of ore, unfit for chlorine making, but employed in the manufacture of steel: 0.5 grm. of ore was employed for each test.

Nitrometer filled with Mercury.	Nitrometer filled with Water.
Cc.	Cc.
36.6 oxygen.	36.4
36.6	36.6
36.9	36.6
36.7	..
37.0	..
Average 36.76	36.53

$$= 28.65 \text{ per cent. MnO}_2 = 28.47 \text{ per cent. MnO}_2.$$

The iron process yielded 28.60 per cent.  $\text{MnO}_2$ . For commercial purposes the iron process will, of course, retain its supremacy, but the nitrometric method is a good check upon the former, and as it takes much less time, it is far more convenient for quick estimations in every-day work.

SESSION 1889-90.

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

Meeting held in the Chemical Lecture Theatre, University College, on November 6th, 1889.

SIR JOHN TURNEY IN THE CHAIR.

THE CHAIRMAN, in opening the proceedings, said it was not a very uncommon thing for men to find themselves in places which they were totally unfitted to fill, and that was the case with himself that evening. When he was asked to become their Chairman he told Dr. Clowes that he knew little or nothing of theoretical and practical chemistry. Unfortunately it had not been his lot to study this important science, and therefore on that occasion he could do little more than preside. As a large manufacturer in the town he had often felt the want of chemical knowledge, and his firm had been stupid enough, like many other people very likely, to go on for nearly 20 years making various articles by rule of thumb. But some eight or ten years ago he did turn his attention to chemistry, to the extent of getting around him men who theoretically and practically understood the subject, and the firm had derived considerable advantage from this step. If this nation desired to maintain its position against foreign competitors we should have to make considerable advances in education. Those advances had begun, and if they were maintained and increased, for there was much to be done yet, the benefit to the country would be certain and great.

# THE DETERMINATION OF SULPHUR IN IRON AND STEEL.

BY L. ARCHBUTT, F.I.C.

THE process of oxidising iron or steel by aqua regia, evaporating to dryness to separate silica, redissolving in hydrochloric acid, filtering, and precipitating with barium chloride, is, when properly carried out, if not the most rapid, certainly one of the most accurate methods of determining the sulphur. The object of this paper is to call attention to certain important fallacies which have crept into the published descriptions of the method, and to describe the simplest and best way of working according to my own experiments.

In a paper communicated to the Chemical News in 1888 (Vol. 58, p. 41), Messrs. Arnold and Hardy stated that the excess of hydrochloric acid used in redissolving after separation of silica is evaporated off "until only sufficient to retain the iron in clear solution is present. The concentrated liquid is then diluted, and the insoluble residue is removed by filtration. The filtrate is next largely diluted and the sulphur is precipitated by means of barium chloride." They then proceeded to bring five objections against the process, of which two are of no importance, and the remaining three may be summarised thus:—1. That excess of acid causes low results; 2. That about two days are needed for an estimation, 24 hours being usually allowed for the precipitation alone; and 3. That the barium sulphate is sometimes difficult to filter, and that it is occasionally impure with iron, the removal of which either involves loss of precipitate or a serious loss of time—all of which objections I will show to be misleading or exaggerated.

Morgan (loc. cit. p. 63), in discussing the above paper, admits that the results are too low if the solution contain excess of acid, and states that the solution when freed from this excess should be diluted to a large volume before precipitation. He also admits that the process takes a long time, but he points out that the results obtained are unsurpassed for accuracy, and that accuracy ought not to be sacrificed for a saving of time.

Blair (The Chemical Analysis of Iron, 1888) says, "redissolve in as little HCl as possible, dilute and filter. Heat the filtrate to boiling and precipitate with BaCl<sub>2</sub>." How far to dilute is not stated, and to heat to boiling would be a risky proceeding unless there were plenty of free acid present. To this free acid there would be no objection, provided the solution be not diluted, but if it be diluted it is of the greatest importance that it should be highly neutral.

These quotations confirm my belief that it is a very general practice with those who use the aqua regia process to make the ferric solution as neutral as possible, and to dilute it considerably before adding the barium chloride. A steel was once sent to me which when tested by this method appeared to contain no sulphur. The solution was so neutral as to be quite dark in colour, but barium chloride produced no precipitate even after standing several days, although the liquid was agitated and passed through a filter paper in order to disturb the equilibrium; yet it was evident there must be some error, because the hydrochloric acid used contained traces of SO<sub>3</sub>. The analysis was therefore repeated in order to try the effect of adding BaCl<sub>2</sub> to the solution without diluting. In this experiment the solution was prepared from 5 grms. of steel and did not exceed 70 cc. in volume; the result was a precipitate of 0.0160 gm. BaSO<sub>4</sub>, which, after deducting 0.0055 gm. due to impurity in the acid, was equivalent to 0.029 per cent. of sulphur in the steel. In addition to increasing the accuracy of the results the reduction in volume of the solution effected a great saving of time, since precipitation was much more rapidly effected and there was less liquid to filter. Accordingly, ever since this experiment was made, several years ago, I have ceased to dilute the solution. In order, however, to obtain some further figures for comparison, the following experiments were recently made. A steel was taken which contained 1.25 per cent. of sulphur, and a highly neutral solution was prepared containing 20 grms. of the sample. This solution was divided, by weighing, into four equal portions, and one portion was undiluted, while the others were diluted respectively to 250 cc., 500 cc., and 750 cc. To each

solution there was added 5 cc. of a 10 per cent. solution of BaCl<sub>2</sub>.2OH<sub>2</sub>. The solutions were all precipitated at 4.30 p.m. and the two most concentrated were filtered next morning; but it was found necessary to allow the others to stand much longer, as precipitation was so slow. The filtrates gave no further precipitate after standing several days.

Volume of Solution.	Weight of BaSO <sub>4</sub> obtained.	= Per Cent. of Sulphur in the Steel.
Cc. 63	Grm. 0.0155	1.25
250	0.0115	1.14
500	0.0330	0.91
750	0.0270	0.74

It will be observed that the quantity of barium salt added was more than ten times the quantity theoretically required, and no more was added to the filtrates. As it has since appeared to be of interest to ascertain whether by adding a still greater relative mass of barium salt complete precipitation could be effected even in a highly diluted solution, another series of four experiments was made, using however a different steel as the supply of the other was exhausted. The steel used this time contained 1.14 per cent. of sulphur, and solutions of it were prepared as before. It is unnecessary to record the details of these experiments, suffice it to say that it was found by adding a sufficient excess of barium salt, and allowing long enough for precipitation, that very nearly all the BaSO<sub>4</sub> could be caused to precipitate even in a highly dilute solution. In each case the final filtrates remained bright and clear after standing several days with an additional 10 cc. of barium chloride solution.

Volume of Solution.	Weight of BaSO <sub>4</sub> obtained.	= Per Cent. of Sulphur in the Steel.
Cc. 70	Grm. 0.0116	1.14
250	0.0386	1.06
500	0.0391	1.18
750	0.0578	1.04

But the experiments clearly prove that there is no necessity for diluting the solution, and that dilution leads to a loss both of accuracy and of time.

Precipitation being therefore effected in a concentrated solution, it became of interest to determine whether free acid is prejudicial. Seven different steels were made the subject of these experiments. Five grms. of each having been dissolved and evaporated as usual to render silica insoluble, the dry residues were dissolved in HCl, and the excess of acid was evaporated off as completely as possible. After adding a little water and filtering, the filtrates were precipitated by BaCl<sub>2</sub>. Side by side with these, duplicate quantities of the same steels were treated in exactly the same way, except that before adding the BaCl<sub>2</sub> each concentrated solution was mixed with 5 cc. of hydrochloric acid (1.10). The results obtained are shown in the following table:—

	Neutral Solution. (60—70 cc.)		Acid Solution. (60—70 cc.)	
	BaSO <sub>4</sub> obtained.	Sulphur.	BaSO <sub>4</sub> obtained.	Sulphur.
		Per Cent.		Per Cent.
1	0.0530	1.46	0.0515	1.42
2	0.0414	1.11	0.0413	1.11
3	0.0415	1.11	0.0415	1.14
4	0.0337	0.93	0.0330	0.91
5	0.0298	0.82	0.0315	0.87
6	0.0245	0.67	0.0245	0.67
7	0.0215	0.59	0.0205	0.55

All the filtrates were tested with more barium solution, but no more precipitate came down. It appears from these experiments that the presence of free hydrochloric acid is not prejudicial to accuracy in a concentrated solution. It is in fact advantageous, since the solution often filters better when acid, precipitation appears to be rather more rapid, and the precipitate when ignited is a purer white. The results obtained agree with, and are an extension of, those recorded many years ago by Noad (Journ. Chem. Soc. 1857, 15), who showed that in decomposing potassium sulphate with barium chloride in a liquid the total volume of which did not exceed 65 cc., the theoretical weight of  $\text{BaSO}_4$  was obtained, whatever the proportion of free hydrochloric acid (1.10) present. These experiments of Noad seem to have been almost forgotten, and it is curious that Fresenius makes no reference to them.

Having thus shown that precipitation should be effected in a concentrated solution of the iron, and that the presence of free hydrochloric acid is beneficial, it remained to determine the length of time necessary for complete precipitation. For this purpose the steel numbered 1 in the last series of experiments was taken, and two separate quantities of 5 grm. were treated as already described, the solution being made acid by the addition of 5 cc. of  $\text{HCl}$  (1.10). Both solutions were heated to about  $200^\circ \text{F}$ ., and to each 5 cc. of the 10 per cent. barium chloride solution were added. One was filtered after standing two hours, and the other after standing three hours, and these were the results:—

	Acid Solution. (60–70 cc.)	
	$\text{BaSO}_4$ obtained.	Sulphur.
Stood two hours .....	*0535	Per Cent. *117
Stood three hours.....	*0519	*113

The filtrates were treated with an additional 5 cc. of the barium chloride solution, and were allowed to stand for 24 hours; only a mere trace of precipitate came down in either filtrate. Precipitation is therefore practically complete in two hours, and possibly in less, but I have not thought it worth while to pursue the subject further, because I generally find it convenient to add the  $\text{BaCl}_2$  over-night and filter next morning.

The following is a description of the method for determining silicon and sulphur:—5 grms. of steel or iron are added to a previously heated mixture of 40 cc. hydrochloric acid (1.10) and 20 cc. nitric acid (1.42) contained in a large lipped beaker. After effervescence has ceased a few crystals of  $\text{KClO}_3$  are added, and the solution is evaporated to complete dryness and heated on the hot plate for at least half an hour, turning the beaker round occasionally so as to dry every part equally. After cooling, the residue is heated with 20 cc. more hydrochloric acid, and is again thoroughly dried. Forty cc. of  $\text{HCl}$  are then added and heated until a clear solution is obtained. The liquid is then cautiously evaporated until a skin begins to form, when the beaker is removed from the plate, 5 cc. of  $\text{HCl}$  are added, and boiling hot water is blown in from a wash-bottle until the hot liquid is about doubled in volume. It is then at once poured on to a 10 cm. filter, which it just about fills, the beaker is rinsed two or three times with a very little more hot water, and the filter is then covered up and allowed to drain, which does not take many minutes. The filter is washed about twice with cold water and removed to another glass, where the rest of the silica remaining in the beaker is rinsed on to it and washed for the silicon estimation. The dark coloured filtrate containing the  $\text{SO}_3$  occupies less than 70 cc. in bulk, is treated with 5 cc. of a 10 per cent. solution of  $\text{BaCl}_2 \cdot 2\text{OH}_2$ , and is either left over-night in the cold, or it is heated and filtered as soon as the precipitate has completely fallen (two hours or less). The solution is filtered, with or without suction, through a paper which has been previously washed with  $\text{HCl}$  (which greatly hastens filtration), and the precipitate is washed with cold water, dried, ignited, and weighed. From the weight is deducted that of the  $\text{BaSO}_4$  obtained in a

blank experiment with the same quantities of  $\text{HCl}$  and  $\text{HNO}_3$ . The precipitate is seldom, if ever, contaminated with iron, though the ash of the paper is generally pink. If there be any excess of iron present it is easily estimated by heating the precipitate with  $\text{HCl}$ , diluting, and making a colour titration with  $\text{KCN}$ .

Some experiments, which are recorded in the following table, were made for the purpose of comparing the results obtained by this method with those obtained by the evolution method. When the  $\text{H}_2\text{S}$  was absorbed in  $\text{HCl}$  and bromine the results were slightly lower, and the same tendency was observed when caustic soda was the absorbent. Alkaline lead solution was next tried, which is a perfect absorbent for  $\text{H}_2\text{S}$ , but the subsequent treatment of the precipitated  $\text{PbS}$  is troublesome. It is difficult to thoroughly wash the precipitate and filter paper without the use of acid, which accounts for the first two results being rather high; and when even very dilute acid is used in washing, traces of  $\text{PbS}$  are dissolved, judging by indications observed in the course of the third experiment with lead. On the other hand if the precipitate be dissolved up in  $\text{HCl}$  and  $\text{KClO}_3$  low results may be caused by the formation of insoluble  $\text{PbSO}_4$ . Ammoniacal cadmium chloride solution gave the best results, but in this case I noticed that in dissolving the  $\text{CdS}$  in  $\text{HCl}$  and bromine minute particles of sulphur were apt to escape oxidation. This may account for the first cadmium result being slightly low. In the next three experiments the few undissolved particles were treated with fuming  $\text{HNO}_3$  or  $\text{HCl}$  and  $\text{KClO}_3$ . The results of the last three experiments with cadmium solution, and the mean of the whole series shows that whether the steel or iron be oxidised direct with aqua regia, or whether the  $\text{S}$  be evolved as  $\text{H}_2\text{S}$ , practically the same results are obtained, which supports the conclusion that a concentrated solution of ferric chloride, whether nearly neutral or strongly acid, has no appreciable solvent action upon barium sulphate in the presence of barium chloride.

Absorbent.	The Steel used contained, when tested by the Aqua Regia Method

#### DISCUSSION.

Mr. J. B. COLEMAN said he had little experience of the direct oxidation method, but had noticed that in precipitating sulphates in hot solutions containing a large amount of iron, the iron came down with, and coloured the precipitate, and it needed an acid to get rid of that iron. He had used the absorption methods, and had tried several absorption agents:—Hydrochloric acid and bromine; alkaline lead solution, and ammoniacal cadmium chloride, and found that

both the latter absorbed perfectly. Bromine was somewhat more difficult and unpleasant. If the direct method were so exact as Mr. Archbutt's paper seemed to show, he should be inclined to try it.

With regard to the effect of dilution upon the precipitation of the sulphate, he had noticed quite recently that in estimating sulphates in spring water, different students obtained varying results with the same water, so that he had considered the water to be very changeable. More recent experiments by students on the effect of greater or less concentration of such waters had led him to believe that in dilute solutions the precipitation of the sulphate was not so complete in a given time as in the more concentrated ones, and he was pleased that a probable explanation of it had been given. He would like to know if Mr. Archbutt had ever found the iron coming down with the barium sulphate?

Mr. WHITELEY agreed with Mr. Coleman as to the colouration of barium sulphate by iron, and had noticed (in connexion with mineral water analysis) the difficulty of getting it to precipitate in very dilute solutions. He had looked upon it as a question of mass, although it might be due to the slight solubility of barium sulphate in certain salt solutions.

Mr. ARCHBUTT, in reply, said he had never found any iron come down at all in cold solution. All he had noticed was that it seemed impossible to wash the filter paper perfectly clean. The ash turned pink, although the precipitate was white. But in a nearly neutral solution the sulphate must not be precipitated whilst hot, or iron would come down. With regard to a comparison of the two methods—absorption and direct oxidation—he had only made the two comparisons which he had mentioned, and the results were nearly the same by both methods. If he were more experienced in the absorption method he might, perhaps, get results exactly the same.

*Meeting held at Bingham's Restaurant, Nottingham,  
on Wednesday, December 11th, 1889.*

MR. LEONARD ARCHBUTT IN THE CHAIR.

# METHODS OF BACTERIOLOGICAL RESEARCH, WITH SOME ACCOUNT OF BRAN FERMENTATION.

BY J. T. WOOD.

BEFORE explaining the use of these simple pieces of apparatus which are required for the investigation of bacteria, I will give a slight outline of the origin and growth of the now widely extended science of Bacteriology.

The word bacterium is derived from the Greek derivative of *βακτηρον*, diminutive, a stick, because the first forms noticed were rod-shaped, but now that all forms, from granules (*micrococci*) to long thread-like forms (*leptothrix*), are known, they are better described by the word "micro-organisms" or the French word "microbe" which was introduced in 1878 by Sedillot. As early as the 17th century Leuwenhoek noticed these organisms, and in 1773 O. F. Müller named two genera *Monas* and *Vibrio*. In 1838 Ehrenberg published "Die Infusionsthierehen als vollkommene Organismen," and about the same time Dujardin was engaged in research on the minute organisms in infusions; they classed the forms which they described as infusoria, and as such, members of the animal kingdom. At that time naturalists had hardly begun to realise that movement was *not* solely the property of animals. It was Cohn (Untersuch. über d. Entwickelungsgesch. d. microscop. Algen u. Pilze) in 1853 who first proved on grounds of morphology and development that bacteria are plants. Nägeli (Ueber *Nosema Bombycis*) in 1857 showed that bacteria or schizomycetes, the German spaltpilze, should be classed with the fungi instead of algae. Since that time investigators have grown apace, and scores of names might be mentioned of able scientists who have

added and are adding to our knowledge of these organisms (Pasteur, Billroth, Klebs, Koch, Nägeli, Zopf, &c.), and bacteriology has become an important science, especially in the field of medical research.

[Mr. Wood here explained the principal methods employed in studying the development and action of bacteria. He illustrated this by describing different media for their cultivation, and exhibited the different pieces of apparatus required, e.g.:—A Leitz's microscope and all accessories; hot air steriliser; hot filter and flask arranged for filtering nutrient gelatine, agar-agar, &c.; cultivation flasks and tubes; damp chamber and plates; potato cultivations, &c.]

After this brief sketch of the method of bacteriological research, I will now show you a few drawings and give you a short account of some bacteria whose action and development I have specially studied, and which occur in the tanning and preparatory processes in which I am engaged. Tanning, to apply the words which Dr. W. S. Squire (this Journal, 1884, 406) used in reference to brewing, has, like all ancient industries, become perfect in the course of ages by pure empiricism. The practical man, warned by failures in one direction or another, learned by sheer practice that method which yielded the best results without troubling himself about the why and wherefore. But the "rule of thumb" processes of tanning, more so than brewing, have shown themselves under the light of scientific investigation to be of a most complex nature, belonging to a domain of organic chemistry very little explored.

In preparing skins for light and soft leathers they are first washed to remove the bulk of the lime, they are then passed through a "bate" or liquid composed of dogs' dung and water at a temperature of between 30°–40° C.; this rather disgusting process has been in use for many centuries, and yet no efficient substitute has been discovered for it, although many different attempts have been made.

The latest, of German introduction, consists in the application of a solution of cresotinic or cresotic acid (oxytoluic acid),  $C_6H_3.CH_3.OH.CO.OH$ .

Skins in the bate lose their plumpness and firmness and become soft and slippery, or "fall" as we term it, and at the same time the last traces of lime not removed by washing are dissolved out. Many of the liquids tried freed the skins completely from lime, but the resultant leather has proved too hard and rough. This failure to find a substitute for the manure bate is, I believe, in a great measure due to the fact that the action is partly caused by bacteria. On examining a "pure liquor," as the bate is called, with a power of about 600 diameters, the liquid is seen to be crowded with bacteria. The illustration (Fig. 1) shows bacteria I have observed at different times

Fig. 1.

Organisms in Bate Liquor.

in bate liquor. They are nearly all motile, possessing flagellæ, and many are putrefactive ferments, or saprophytes. I have isolated in a plate cultivation several species of bacillus, which liquefied the gelatin. This explains why skins which

are left too long in the bate lose weight and even fall to pieces.

This destruction of skin is one of the great dangers in leather manufacture; frequently, small portions of the fine surface or "grain" of the skin are attacked by the bacteria and eaten away, so that the leather is covered with lines and markings, or "flaked." I have not thoroughly investigated the various microbes contained in it, but amongst others are *Bacterium Termo*, *Bacillus Subtilis*, *Micrococcus Fulvus*, and probably *Bacterium Free* of Cohn. The liquid is usually slightly alkaline, and ammonia and other gases are given off in small quantities.

After bating, the skins go through a truly fermentative process known as "drenching."

They are placed in vats containing a mixture of bran and water, about 0.4 per cent. of bran, at a temperature of 30°–35° C. This ferments vigorously for 18–24 hours, with evolution of considerable quantities of a gas and formation of weak organic acids, which have a slight swelling or "filling" action on the skin, and cleanse the pores and make it in a fit condition to receive the tannin. On examination with a high power of the microscope, the liquid is seen to be crowded with active bacteria.

Fig. 2 is a drawing of the organisms seen in the "drench" in the early stages of the fermentation, mag. 1,000 diameters.

Fig. 2.

Organisms in Bran Liquor. Mag. 1,000 diam.

This was taken from a vat that had been started about three hours; the bacteria form chains, the short chains (like the pairs or dumb bells) are motile, but do not move very rapidly. As the fermentation proceeds these form longer chains (Fig. 3), some of which are very beautiful objects. The other

Fig. 3.

Chains of Bran Ferment. Mag. 1,000 diam.

organisms shown in the figure are probably introduced along with the skins from the bate liquor, and later on, as the nutriment of the bran ferment becomes less, they begin to develop (Fig. 4), first causing butyric fermentation and

Fig. 4.

Bran Fermentation, advanced stage. Mag. 1,000 diam.

finally putrefactive fermentation, so that the skins are rapidly destroyed. The butyric acid formed by these bacteria does not of itself attack or destroy the skin, as the quantity formed is not sufficient; the destruction of the skin is caused by other forms (probably the bacilli above mentioned), which attacks it directly. The fermentation does not appear to have been thoroughly investigated, and I had always thought that the gas given off was carbon dioxide; one day on introducing a lighted taper into a tube full of the gas, expecting to see it extinguished, to my surprise the gas sharply exploded. This was due to its admixture with air, for, on collecting another tube full, and carefully lighting it, mouth downwards, the gas burned with a bluish flame. It contains carbon dioxide and hydrogen or methane and other hydrocarbons, and has a peculiar disagreeable smell. About 1 litre of gas is evolved from 20 litres of the fermenting liquid, that is, 80 grms. of bran give a litre of the gas in the 18–24 hours required for the fermentation at the temperature of 30°; the life of the microbes themselves is much longer.

I first tried to isolate the special ferment, which causes this fermentation, by plate cultivations with the nutrient gelatin of Klein's formula, but, after many attempts, that the bate organisms, bacilli, &c. developed, instead of the one of which I was in search.

The first pure cultivation I obtained was by the fractional method.

A very minute quantity of liquid from a normally fermenting vat was introduced by means of a freshly made capillary pipette, into a sterile tube containing bran infusion; this was placed on the incubator, and the organism in greatest abundance, *i.e.*, the one causing the fermentation, develops first; as soon as the liquid in the tube was observed to become cloudy, indicating the development of the bacteria, a minute portion was used for inoculating a fresh tube; this second "attenuation" was then carried on to five or six more tubes.

I found the fifth tube to contain one species of bacteria, giving invariably similar growths in other tubes, and producing the same fermentation in sterile bran infusions. They are active mostly in the form of pairs or dumb bells, each cell  $0.75 \mu$  by  $1.25 \mu$  (Fig. 5), varying slightly in size, some forming chains; those on the surface become surrounded by a kind of jelly (Fig. 5) and form an iridescent pellicle on the surface of the liquid, the zoogloea form. When the nutriment of the liquid is exhausted this film, which is not very dense, sinks to the bottom, and the liquid above becomes somewhat clear. I have followed the development up to this point, and have seen no formation

of spores, that is true or endospores; the sediment consists of segments of the cells, which act as spores (arthrospores), and if introduced into a fresh nutrient medium, reproduce and carry on the fermentation. After the fermentation the liquids, both in the vats and tubes of pure cultivations, are always slightlyropy. Its action and morphological appearance

Fig. 5.

Bran Ferment from Pure Cultivations. Mag. 1,000 diam.

in other nutrient media are different. In a bran infusion containing glucose it forms long thread-like or leptothrix forms in one stage; the forms on the surface are usually most regular in size, but the ferment is not aerobic, active forms being found in almost equal abundance in every part of the liquid. It grows *very well* on sterile potatoes, and appears as a white-brown slime spreading on either side the track of the needle by which the inoculation was made.

This rapid and easy growth seems to show that the ferment can utilise the starch in its undissolved and unchanged condition, and explains why a vat made up with bran and cold water will ferment the same as one in which the bran was first scalded, only much more slowly. The same gas is, however, given off, and the fermentation appears in every way to be the same. On testing the liquids both before and after the fermentation with Fehling's solution no reduction takes place, showing that there is no change of the starch into maltose.

On testing with iodine all freshly made up vats and sterile tubes give the blue starch colouration strongly; after the fermentation they do not give it, showing that all the starch is decomposed.

A sterile tube (which gave the blue iodine colouration) was inoculated from one of the tubes of pure cultivation and tested every day by means of a drop withdrawn by a sterile pipette on a white plate. At the end of the seventh day the iodine reaction did not appear, showing that all the starch was decomposed. This occurs much sooner in the vats, owing to the large amount of the ferment acting.

The total constituents per 100 cc. of the infusion are:—

	Grm.
Starch .....	*176
Cellulose .....	*068
Fibrin .....	*03
Fat .....	*016
Ash .....	*626

It will be seen that the starch must be the principal body decomposed, the next being the cellulose.

Tappiner (*Zeitschrift für Biologie*, 24, 105) has shown that certain ferments decompose cellulose with the formation of fatty acids and evolution of carbon dioxide, hydrogen, and methane, the organisms requiring some nitrogenous matter for their nutriment. The bran ferment appears to decompose the starch and part of the cellulose of the bran, the fibrin and other albuminous bodies serving for its nutriment. The skins have no influence and under ordinary

circumstances take no part in the fermentation. A vat filled with cloths instead of skins ferments in exactly the same way as vats filled with skins. Some bacteria, when grown in liquids containing starch, are stained blue by the application of iodine, showing that the starch has diffused into the cells in a soluble form. The bran bacteria do not give the blue iodine reaction in any stage of their growth, which I have yet observed. The starch is decomposed, but no soluble amyloid body which is coloured blue by iodine exists in the cells. In appearance the ferment much resembles the viscous ferment of wine mentioned by Pasteur  $1\mu$ — $1.2\mu$ , in length, and in its action the mucic fermentation investigated by Kramer (this Journal, 1889, 811), and may cause the slight ropiness of the liquids in a similar way. This viscous matter is a modification of cellulose; carbon dioxide is given off but no hydrogen in the mucic fermentation (Kramer).

Not much can be surmised from the form alone, as it varies according to the nutrient conditions and from other causes; in the present case I have shown the forms of my pure cultivations to vary considerably when grown in different media.

It will be seen from the constitution of the fermenting liquid, that the fermentation I have just described, and the reactions which take place, are exceedingly complicated, and at present I am unable to state the exact manner in which the ferment acts, much less to give the chemical equations representing the decompositions effected.

The nature and constitution of starches and albuminoids is one of the most difficult problems of organic chemistry, and I can get no reliable information about the particular fermentation I have introduced to you. I am hoping to be able to follow the subject and to have the pleasure at a future meeting of giving a more complete account of the action and products of the bran ferment.

#### DISCUSSION.

Professor CLOWES said he wished to congratulate one of his old students on the excellent paper given. It was a source of pride and satisfaction to him that an old student of University College had sufficient enthusiasm not only to apply some of the knowledge gained there but to so greatly extend it that he was able to bring before the Society new matter, and to launch out upon a research likely to have most important results. He supposed that Mr. Wood's object was to find out the organisms producing the changes he desired in tanning, to cultivate these and then use them in the pure state so as to carry on the work with certainty and without the interference of other organisms. Anyone who had read Pasteur's researches on "beer" would have some idea as to what might be done by successful research of this kind.

Mr. J. B. COLEMAN expressed a doubt whether a 0.4 per cent. bran extract was sufficiently strong in which to determine the products present after fermentation. He thought that if dextrin, glucose and maltose were the intermediate products formed a stronger solution was necessary: of course for starch the iodine test was sufficiently delicate. He also questioned if it were correct that solid starch was incorporated, as such, by the organism. It was known that in similar solutions acids were always present after the fermentation, and that these and the small amount of albuminous matter present had the power of forming a modified and soluble starch; this modified starch thus forming a medium in which the ferment can grow. It was known there were acids formed in the present instance, and that might, therefore, be the explanation of the process.

Mr. WOOD said that probably the explanation just given would be correct. He certainly had proved the absence of starch in tubes, on potatoes and in the vats after fermentation, and it was therefore certain that the ferment did in some way destroy the starch, this being also evident from the large volumes of gas formed viz:—about 100 litres from a vat of about 1,500 litres capacity. As to what other bodies were formed it was impossible to give a definite opinion as the medium was so complicated.

Mr. WHITELEY said that Mr. Wood's remarks emphasised the necessity first of obtaining a pure cultivation, and second of observing its effects in simpler media.

Mr. WOOD said that, acting on the advice of Mr. A. Brown, he had already in part done this and obtained what he considered to be a pure cultivation, but he had yet to try its effects successfully on the different constituents of bran, a research which involved more time than he had yet had at disposal.

The CHAIRMAN asked as to the relative value for this class of work of a low priced  $\frac{1}{2}$ th immersion object-glass as compared with a dry glass of lower magnifying power but of the very best make, such as a  $\frac{1}{2}$ th by Powell and Lealand. He also suggested that the difficulty of filtering the media quickly might be got over by using suction.

Mr. SMALL asked if other nutrient materials had been tried instead of dung for the bates? Would other liquids have a similar effect?

Mr. WOOD: Such bates had been tried, *e.g.*, an American bate containing principally glue and glucose; but the greater proportion of new bating materials were simply devices to dissolve out lime. A solution of acid had, he believed, been tried, but was of no practical use for light skins.

MR. R. R. TATLOCK IN THE CHAIR.

## THE FIXATION OF NITROGEN.

BY CHARLES A. FAWSITT, F.R.S.E., F.C.S.

THE "fixation of nitrogen" is a problem which has for a long time exercised the minds and taxed the ingenuity of chemists. It is a subject of great importance from a commercial point of view, but up to the present time no satisfactory solution has been found—at least, one which will

allow of it being worked economically on a manufacturing scale. The most likely compounds to be formed if its fixation is satisfactorily effected are cyanogen or ammonia or an oxide of nitrogen.

Quite recently several valuable contributions have been made to this subject, including those by Mond, Readman, and Breneman. The latter paper, which appeared in *American Jour. Soc. Chem.*, contains a very complete history of the subject, and has been of great service to me in writing this paper. I do not intend to give a complete history of the subject, as it would occupy too much time, and could not be of interest, as much of the work done has been a repetition of some published previously. In fact, all along it has been very much a case of "follow the leader;" and to show how little progress has been made, it is sufficient to mention that the trials which were made 50 years ago more nearly approached a solution of the difficulty than anything which has since been done—at least, that has been made public.

Before passing on to the "fixation of nitrogen," I will speak for a moment of the properties of nitrogen. This element, as you are all aware, is of great importance. By its presence in the atmosphere as a diluent, we are enabled to prolong our stay in this world to a far longer period than if we had an atmosphere richer in oxygen, and no gas could be substituted for it without exerting an influence prejudicial to animal and vegetable life. As regards its chemical properties, it is distinguished by its inertness, not showing, under ordinary conditions, a marked affinity for any other element; but it is owing to this inertness, and its tendency if combined to recover its freedom, that gives such valuable properties to our explosives, in which the nitrogen and oxygen are only in a feeble state of combination, thereby causing a state of unstable equilibrium, and a slight disturbing cause is sufficient to bring into play the stronger affinities of carbon and hydrogen, setting free the nitrogen, which helps very materially to give the explosion such sudden effect.

Nitrogen, as it exists in the atmosphere, is essential to animal and vegetable life, although it is difficult to trace its action. It exists in all albuminoid bodies, and in many organic substances is the chief component. In the mineral kingdom it exists as  $\text{KNO}_3$  and  $\text{NaNO}_3$ , which form the starting point for nearly all our nitrogenous compounds.

*Fixation of Nitrogen in Air.*—In the atmosphere we find several nitrogenous compounds, nitric acid, carbonate, nitrite, and nitrate of ammonia, which play a very important part in the economy of nature even, although the actual quantities are proportionately small to its other constituents. The ammoniaical compounds may partly be accounted for by decomposition of organic matter; but the chief agent in their production is electricity, and several processes have been based on conditions under which it was thought they must be produced in the atmosphere. Schönhein accounts for the formation of  $\text{NH}_4\text{NO}_3$  and  $\text{NH}_4\text{NO}_2$  by supposing that under the influence of the electric discharge the molecule of nitrogen splits up at the same time as that of  $\text{H}_2\text{O}$ , and we get a direct combination,  $\text{N}_2 + 2 \text{H}_2\text{O} = \text{NH}_4\text{NO}_2$ . Again, if a mixture of nitrogen and oxygen are submitted to a series of electrical discharges, we get nitrous fumes, which, in contact with moisture, forms nitric acid; and it may depend very much on the amount of the moisture in the atmosphere whether we get  $\text{HNO}_3$  or  $\text{NH}_4\text{NO}_3$ .

Analogous somewhat to the fixation of nitrogen in air is the formation of  $\text{NH}_4\text{NO}_3$  when a mixture of nitrogen and hydrogen is burnt.

We have also nitrogen combining with acetylene under the influence of electric discharge  $\text{N}_2 + \text{C}_2\text{H}_2 = 2 \text{HCN}$ , which is interesting from the fact that if the electric discharge between two poles of gas carbon was passed through a dry mixture of  $\text{H}_2$  and  $\text{N}_2$  it would most likely be formed from its elements. From these examples you will notice that a certain amount of work in the form of heat has to be done before the nitrogen molecule is dissociated so as to allow of it combining with the other elements.

*Nitrides.*—When certain elements are heated in nitrogen gas a combination is effected, and we get a nitride. For instance, we have boron, silicon, tungsten, and titanium

nitrides, and these compounds when heated in steam decompose, giving off their nitrogen as ammonia. It has been advanced as a solution of the problem as to how ammonia is evolved from the lagoons in Tuscany, that boron nitride is formed and decomposed, but it is more likely to be the result of heat on organic matter.

I shall now endeavour to bring under your notice the more important work which has led up to the attempts to manufacture cyanides, &c. by fixing nitrogen.

As early as 1813 a white substance, supposed to be a chloride, was found as a deposit at some blast furnaces in Germany, but on subsequent testing was found to contain a considerable proportion of cyanide. This was scarcely credited, but received ample confirmation two years later, when similar deposits were found at some furnaces which had been erected by Neilson near Glasgow. This salt on analysis gave 43.5 per cent. KCN and 46.5 per cent.  $K_2CO_3$ . The alkaline properties of this substance had previously been discovered by the workmen, who were in the habit of taking it home to their wives as a substitute for soap powder.

Considerable interest now began to be centred in the matter by chemists, and two of the most noted, Messrs. Bunsen and Playfair, made an extensive research in order to find, if possible, a solution of the problem. Their investigations were carried out on a blast furnace at Alfreton, which seemed to have been specially designed to produce KCN, as it produced no less than 2 cwt. per day. They proved moreover that it was produced in the lower and hottest part of the furnace, whilst it was decomposed into  $N_2 + CO$  in the upper part, acting evidently as a reducing agent on the fresh ore. They analysed the gases drawn from different heights in the furnace and found that the absorption of nitrogen was very considerable where the KCN was formed. The relation of nitrogen to oxygen being 79.2:22.8, whereas in ordinary air it is 79.2:20.8. It was thought by certain chemists that there had not been a "fixation" of atmospheric nitrogen at all, the nitrogen in the KCN coming from the coal. In order to prove the truth of this, two experiments were made, one in which a quantity of sugar charcoal impregnated with chemically pure carbonate of potash was heated in a gun-barrel in a stream of pure nitrogen gas, and the other in which a similar mixture in a similar tube was heated in a stream of pure  $CO_2$ . The latter experiment produced no cyanide, the former a very considerable quantity, proving conclusively that nitrogen is fixed by alkalis carbon as cyanide.

Someone may be tempted to ask where the potash came from in the blast furnace in order to produce 2 cwt. of KCN per diem. It was found to come from the ore and coal, which contained 0.7 per cent. and 0.07 per cent. respectively.

Several eminent chemists, including Berzelius, Marchand, &c., now came forward, who said that, in order to produce cyanide from alkalis carbon, it was necessary to have moisture present, the reason assigned being that ammonia had to be produced in the first place. At this time it was well known, being mentioned by Bunsen and Playfair, that cyanides were easily produced by passing ammonia over alkalis carbon. This theory received considerable support, but subsequent experiments did not confirm it, and it seems strange how it can have received any support, as, in order to produce ammonia, we must suppose that cyanide is produced in the first place, which simultaneously produces ammonia in presence of steam; but given a certain quantity of cyanide produced, we cannot expect to receive a further quantity after it has been transformed into ammonia, and again into KCN.

Delbrueh now added another important link by proving that cyanogen was formed when nitrogen was passed over heated carbon. I think, however, that this requires confirmation, as we shall see further on.

Chemists now began seriously to consider the possibility of manufacturing cyanides, ferrocyanides, and ammonia. An inexhaustible supply of nitrogen was to be got from the atmosphere for next to nothing. The working also of the process did not appear to offer insurmountable difficulties, and, on the other side, a large demand existed for ferrocyanides,

the price for which was very much higher than at the present time.

Before bringing under your notice a few of the principal patented processes, it will be as well to mention the available sources of nitrogen.

1st. We have the atmosphere.

2nd. The waste gases from the vitriol chambers.

3rd. The waste gases from the absorption towers in the ammonia-soda process, the  $O_2$  in which, I am informed by Mr. Mond, can be reduced to less than 1 per cent.

4th. The ordinary products of combustion: for example, furnace gases.

5th. The waste gases from the manufacture of oxygen by barium oxide method, which I am told consist practically of pure nitrogen.

If air is used we must remove the oxygen, or else it would convert all the cyanide into cyanate, and, finally, into  $N_2 + CO$ . In the preparation of ammonia, the presence of cyanate is not hurtful, as it gives ammonium carbonate with steam. To effect this removal, carbon and iron are usually used, but with the latter it is difficult to free air entirely from  $O_2$  without using a very large apparatus, increasing very much the cost of working.

It can be completely combined with carbon, but the  $CO$ , acting as a diluent, impedes the production of cyanide, &c. Adler proposes barium or calcium sulphide, but this would be troublesome and expensive. A lower oxide of nitrogen has been proposed, but never, so far as I know, successfully used.

The processes proposed for the manufacture of cyanides, ferrocyanides, and ammonia may be divided into four classes:—

1st. By passing nitrogen or nitrogen plus aqueous vapour or nitrogen plus carbon monoxide over carbon impregnated with the salt of an alkali or alkaline earth.

2nd. Passing ammonia over carbon or alkalis carbon.

3rd. Those in which electricity is used as the agent for effecting a combination of nitrogen and hydrogen.

4th. Those not classed under the other three heads.

#### CLASS 1.

The first patent taken out in this country was by Newton, 1843, for a foreigner, and as the Possoz and Boisiere's experiments were being conducted in France at this time, it strikes me that it was for their process. At any rate, as the two processes are identical in details, it will suffice, seeing it is more complete, if I describe the work done by the latter.

At this time Possoz and Boisiere were hard at work in France with a small apparatus, and had managed to turn out 15 tons of prussiate of potash in a year, but owing to the high price of coal and the want of good fireclay they resolved to transfer their operations to Newcastle, where the matter was taken in hand by Messrs. Bramwell and Hughes, who imparted a great amount of skill and energy in carrying out the process, leaving no stone unturned which would conduce to its success. From the experience previously gained in France it was confidently expected the process would turn out successful, and great interest was centred in the trial.

The retorts were vertical, 10—12 ft. long, 2 ft. in diameter. The upper part was made of fireclay 9 in. thick; the lower part of iron, where the cyanised charcoal was cooled. Slits were cut in the retorts so as to allow of the furnace gases being drawn through the mass of alkalis carbon in the retort. It was found before this was done that the centre of the mass was too cold. The retorts could be heated to a temperature at which the best Stourbridge fireclay softened. The method of procedure was to fill the retorts with wood charcoal which had been impregnated with 20—30 per cent. of  $K_2CO_3$ . Air was now drawn through the retorts until the cyanising process was deemed complete, when the contents of the retort were lowered by means of a revolving screw into the cooling chamber. When the next batch was cyanised that already in the cooling chamber was by the screw lowered into a tank containing a solution of ferrous sulphate, where it was converted into prussiate of potash. The charcoal after lixiviation and drying was ready for

another operation. When the conditions, such as flow of nitrogen, heat, and percentage of  $K_2CO_3$ , &c. were favourable, 50 per cent. of the theoretical yield was obtained, and the yield of prussiate from a bench of eight retorts was two tons per week. The quality was very fine and obtained a ready sale. These trials were commenced in 1844, and continued uninterruptedly until 1847, during which time thousands of pounds were lost. But although it was a failure, Messrs. Biamwell and Hughes deserve great credit for having attacked the problem with a determination and perseverance rarely seen.

The chief causes of failure were—1st. The loss of potash, three parts being lost for one part of prussiate made. This loss could partly be accounted for, as some combined with the material of the retort and some was left in the charcoal after lixiviation, but over and above this there was a loss which was never accounted for. 2nd. The large amount of charcoal which had to be lixiviated for a small return of prussiate told heavily against its success. 3rd. The wear and tear of the plant was very great, chiefly owing to the high temperatures employed.

From the experience gained it was thought that some of the KCN was produced from the nitrogen in the charcoal, as when alkalis charcoal was heated in air-free space they still found cyanide, but as wood charcoal contains only a very small percentage of nitrogen it could not have amounted to much.

The yield of KCN varied with the temperature of the retorts, being greatest when hottest. The yield was also greater with wood charcoal than with coke, also with potash than soda. The yield of prussiate per unit of potash was greater than by the old process. Great stress was laid on the fact that water must be excluded from the apparatus, as they found that when present the yield of cyanide fell proportionally. It seems strange that about this time two patents were taken out, in which the presence of water was claimed as an improvement. Ten years later an extensive trial was made at Odenwald, in Germany. Coke balls of uniform size were saturated with  $K_2CO_3$  and heated very strongly in vertical cylinders, but although the heat was very strong very little cyanide produced, and the process was abandoned. It was thought that the heat had not been sufficiently strong, as on looking in the retorts the centre of the mass was always very much cooler than the part next the inside surface of the retort. I pass over several patents as there is no feature of interest. In 1862 Marguerite and Sourdeval patented what was at the time considered a valuable improvement, namely the substitution of barium carbonate for those of the alkalis, the great point claimed being its infusibility, thereby presenting a much larger surface to the action of the nitrogen gas, and not "clogging" up the pores of charcoal. This process received a fair trial, but was given up as a failure. In 1882, L. Mond patented a certain form of apparatus in which barium carbonate is used, but as his experience is published in the last July number of our Journal it will be better for those interested to refer to it. But it is very satisfactory to note that he speaks so hopefully of the future of the process.

Some years ago I conducted a series of trials at St. Rollox with a view of producing ammonia by acting on alkalis charcoal with nitrogen derived from the atmosphere, but the result was to add another to the long list of failures; but although apparently there have been so many, the experience gained in time past may help in some measure to solve the problem in the future.

My first experiments in 3-in. and 4-in. M.I. tubes gave such good results, often getting 50 per cent. of the theoretical yield of ammonium sulphate, that it was deemed advisable to erect a larger experimental plant consisting of 10 vertical retorts 6 in. diameter, 9 ft. long, 2 in. thick. The drawings will explain the construction and working of the same. The alkalis charcoal, containing 25–30 per cent. carbonate of soda, was charged into the top of retort A, which was provided with a tight-fitting door, the charge having fallen into the part of the retort exposed to the fire B, was heated there for 4 to 6 hours and then lowered by the screw C into the cooling box D, another charge taking the place of the one drawn down. After remaining in the cooling

box until another charge was to be lowered, it was taken out at the door E into luted iron boxes and hoisted up to be transferred to the retorts where it was steamed, the ammonia passing over to a vessel containing sulphuric acid, where it was absorbed and worked up in the usual way. The nitrogen was supplied from a blower through the pipe H at

Fig. 1.

Fig. 2.

Fig. 3.

the rate of about 1–2 cubic feet per minute for each retort, and in order to extract the oxygen it was on its way passed through two vertical retorts 9 ft. long and 9 in. diameter, filled with iron turnings and kept red hot. It was found, however, that it was very difficult to deprive the air of all its oxygen, and it usually gave 3–5 per cent.  $O_2$ . The apparatus was worked continuously for some months, but did not yield  $(NH_4)_2SO_4$  which anything like paid working expenses, and which had been thought possible from the smaller trials. There was no new feature in the process other than the construction of the apparatus, and as one looks at it now it would have been much better to have profited by previous experience. The chief cause of failure lay in the fact that a good conversion could not be obtained in the C. I. retorts as they would not stand the temperature required. The loss of alkali also amounted to 10–20 per cent., but if special arrangements were made this could be all accounted for. The

cyanised charcoal contained about equal quantities of cyanide and cyanate owing to the presence of  $O_2$  in the nitrogen. In my small trials I did not find barium carbonate give so good a yield as soda or potash.

The best results were always obtained with a strong heat; in fact, when the exit pipes contained a deposit of cyanide which had volatilised, it was conclusive evidence of a good experiment. The reactions involved in the formation of ammonia in the above process are usually condensed into one,  $2 KCN + 4 H_2O = K_2CO_3 + 2 NH_3 + CO + H_2$ , whereas it would be more correctly expressed by showing it in two stages, formate of potassium being formed in the first stage,  $KCN + 2 H_2O = KCHO_2 + NH_3$ .

Then  $2 KCHO_2 = K_2CO_3 + CO + H_2$ .

From cyanate only one reaction is possible—

In 1887 Siepermann conducted a series of trials in order to find out which temperature was most suitable for the production of cyanides, using alkalis carbon, and his results were that a red was better than a white heat. Weldon also, in provisional patent, 1877, says it was owing to the strong heats employed that better results had not been obtained. I think the mass of evidence is contradictory, Possoz and Boisiere's experiments being very conclusive.

The conditions existing in the blast furnace seem to furnish a good basis for the preparation of cyanides, and it has been proposed to erect one with this end in view. It has not been very satisfactorily settled as to what is the

reaction which takes place when nitrogen acts upon alkalis carbon. It is usually expressed so—

but this I am afraid tells us very little of the real truth. There are three theories advanced; one is that nitrogen in contact with highly heated carbon is converted into cyanogen, and on the reduction of the salt of the alkali or alkaline earth it combines with the metal to form cyanides. What supports this theory is that the temperature required to form KCN is lower than for NaCN, so the temperature for the reduction of  $K_2O$  is lower than that for  $Na_2O$ .

Another theory, advanced first, I think, by Berzelius, is that potassium acetylene ( $C_2K_2$ ) is first formed, and this in presence of  $N_2$  forms KCN. But it seems strange that if such a compound as  $C_2K_2$  exists that it has never been prepared, as it must be produced with facility, and not only the potassium compound, but also that of sodium, barium, &c.

Until recently the first theory appeared to me to be the most likely, as the formation of cyanide always proceeded quickly when the reduction temperature was reached, and taking into account the statement of Delbrück that cyanogen is easily prepared by passing nitrogen over heated carbon, it seemed to be almost proved. There was one point, however, which seemed to be against it, and that was the fact that no method for producing metallic barium by heating the carbonate with charcoal is known, and still the formation of  $Ba(CN)_2$  proceeds easily. In order to satisfy myself as to whether cyanogen was produced in the way just stated, and imitate, if possible, the reaction as near as possible, I asked my co-worker, Mr. Anderson, to carry out an experiment on the following lines:—Having procured a stock of

Fig. 4.

pure nitrogen by shaking up air with pyrogallate of soda, it was passed out of A through (see Fig. 4) a drying tower B, then over wood charcoal heated to a white heat in the iron tube C, 3 ft. long, 1½ in. diameter. The gas, which should contain CN, was now passed through a bulb tube E containing a piece of metallic potassium in bulb F, and when it was deemed that the whole apparatus was full of nitrogen the potassium was heated strongly. A moderate current of gas (about 30 litres in all) was kept up for two hours. The gas on leaving bulb F passed through a flask G containing water. At first, when the potassium melted, it remained perfectly clean on the surface, but when the temperature rose to the boiling point it gave off a white vapour consisting principally of potassium, but it gradually, where the heat was strongest, assumed a green colour, and finally almost black. I think it was owing to a little impurity in the potassium, as on heating a similar piece in pure  $N_2$  the same appearances were observed. On testing the deposits in different parts of the tube metallic potassium was found to be present; also carbon, but not a trace of cyanide. This experiment was repeated with sugar charcoal with an exactly similar result. In order to ensure the charcoal in each case being free from enclosed air, undecomposed organic matter, &c., the iron tube containing it was heated very strongly for two hours in a stream of nitrogen before starting the experiment. At present, therefore, an explanation of the reaction is wanted.

A third theory has been proposed as possible, namely, that a nitride of potassium is produced which combines with carbon to form KCN, but if such is the case it seems strange that it has never yet been prepared. It is possible

that the compound  $K_2C_2O_2$  is produced as in the manufacture of  $K_2$ , and this in presence of an excess of carbon and nitrogen is reduced,  $N_2$  at same time taking place of  $O_2$ . This would amount to very much the same as the theory on which  $C_2K_2$  is said to be formed.

## CLASS 2.

Under this we find that Scheele in the last century obtained KCN by heating sal-ammoniac,  $K_2CO_3$ , and charcoal, and was followed by Clouet and Kuhlmann, who found that cyanogen was produced by passing ammonia over heated charcoal,  $4 NH_3 + 3 C = 2 NH_4CN + CH_4$ .

It was well known that  $NH_3$  passed over alkalis charcoal produced cyanide, Graeger having obtained 93—95 per cent. of the theoretical yield of cyanide by passing ammonium carbonate over alkalis charcoal contained in iron tubes 1½ in. diameter. In 1857 Kamrodt tested the latter idea and proposed to utilise the waste gases produced in the manufacture of prussiate by the old method. Brinquell about this time brought out a process in which animal matter and alkali were dispensed with, advantage being taken of Clouet's and Kuhlmann's idea in which  $NH_4$  was merely passed over heated charcoal. If  $NH_4CN$  could be easily produced in this way its transformation into KCN or prussiate could easily be effected.

Fleck says that he obtains 95 per cent. of the theoretical yield of cyanide from ammonia by treating a hot mixture of charcoal, sulphur, and potash with  $(NH_4)_2SO_4$ , the waste ammonia being again utilised, the sulphocyanate of potash reduced to cyanide by heating with iron filings. This

process on testing afterwards was found unsuccessful in practice.

Romilly found that on allowing illuminating gas to bubble through ammonia and afterwards igniting and allowing the flame to impinge on the surface of a drum revolving in a solution of  $\text{KHO}$ ,  $\text{KCN}$  was produced. Still later we have the experiments of Readman, detailed already in the last October number of this Society's Journal.

Early in 1843 a patent was taken out by Laming for the production of cyanides by passing ammonia over red-hot charcoal. In 1860 Lucas patented a process for impregnating charcoal with  $\text{K}_2\text{CO}_3$ , introducing the mixture into two vertical retorts which were strongly heated, ammonia was now passed in, when the potash was converted into cyanide. If prussiate was wanted iron filings were added to the mixture of  $\text{K}_2\text{CO}_3$  and charcoal. This process was, I believe, worked on a considerable scale, but proved a failure.

Webster impregnates wood with  $\text{K}_2\text{CO}_3$ , then chars the same in retorts and passes in  $\text{NH}_3$  for the preparation of cyanides.

### CLASS 3.

Under this head numerous processes have been patented, following very much on the same lines, but so far as I know none have been worked on a manufacturing scale. I select two or three from the number. Chisholm passes the products of combustion through heated retorts containing carbon, steam being at the same time injected. He says that the nascent hydrogen combines with the nitrogen to form ammonia, but if the combination is not complete the gases as they leave the retort are submitted to an electric discharge which is said to be of great service.

Müller prepares hydrogen by leading steam over heated carbon, and stores it in a gasometer. Nitrogen is likewise prepared by passing air over carbon, absorbing the  $\text{CO}_2$  produced, and storing the nitrogen. The gases, in proportion 3 vols.  $\text{H}$  1 vol.  $\text{N}$ , are now passed through a tube, being at the same time subjected to an electric discharge when, he says, ammonia is formed.

Young submits  $\text{H}_2$  and  $\text{N}_2$  to action of electric discharge in presence of aqueous vapour; he claims this as a decided advantage.

### CLASS 4.

Under this head we have a large number of different ideas brought out. Solvay proposes to impregnate fuel with calcium chloride and mix it with limestone or other base. The mixture is then charged into a cupola, steam and air being admitted through the incandescent fuel. Chloride of ammonium is now formed and condensed. It is claimed that by the use of a decomposable chloride the limits of temperature for the successful carrying out of the reaction are not so narrow as when alkalis carbon is used in the ordinary way.

Bassett produces boron nitride by heating a borate with charcoal and alkaline carbonate, the reduction of the latter salt to metal bringing about the formation of amorphous boron, which in an atmosphere of nitrogen forms boron nitride. This compound is then decomposed by heating in presence of aqueous vapour and the ammonia absorbed in the usual way.

Dufrene passes air or nitrogen over charcoal which has been soaked in platine chloride and heated to produce finely divided platinum. Hydrogen is passed over the prepared charcoal under pressure, when ammonia is said to be formed.

Twineh states that he gets nitrogen into nascent state by depriving air of its oxygen with nitric oxide. This nitrogen is then brought into contact with nascent hydrogen made by passing steam over a metal or by action of zinc on an alkaline hydrate, when  $\text{NH}_3$  is formed. There are very many others, but as they are for the most part comprehended under those already mentioned it is of little use detailing them.

*Future of the Process.*—In conclusion it will be advisable to consider whether or not there is any hope of the process in the future, and, if asked, I should answer in the affirmative. As previously mentioned, Mond takes a hopeful view of the process in which barium oxide is used as the

base. Taking present prices as a basis I should say there is a very much better chance for success if cyanide or ferrocyanide are the products aimed at, as shown by following figures:—

1 ton of $\text{N}_2$	will produce	4.7 tons	$(\text{NH}_4)_2\text{SO}_4$	at 12% per ton=	567.
1 " $\text{N}_2$	"	5.0 "	$\text{K}_4\text{Fe}(\text{CN})_6$	" 63% "	=315.
1 " $\text{N}_2$	"	4.6 "	$\text{KCN}$	" 162% "	=745.

You will see that the  $\text{N}_2$  converted into  $\text{KCN}$  has 15 times, and if into ferrocyanide, nearly six times the value that it has if turned into sulphate of ammonia, and as new sources of application for  $\text{KCN}$  have lately arisen, and thereby increased the demand in a very marked degree, it seems as if attention should be more specially directed to this article. It seems strange converting  $\text{K}_2\text{O}$  or  $\text{BaO}$  into cyanide for the production of  $\text{NH}_3$  when cyanide commanding such a high price has to be decomposed into ammonia, an article of comparatively little value. As to which base is the best for the preparation of cyanides, opinion is divided generally between  $\text{K}_2\text{O}$  and  $\text{BaO}$ ; of course it depends very much on whether ammonia,  $\text{KCN}$ , or prussiate is to be the ultimate product. If  $\text{KCN}$ , taking into account the various results, one would fix on  $\text{K}_2\text{O}$  as if  $\text{BaO}$  were used.  $\text{BaCN}$  would require to be reconverted into  $\text{KCN}$ , which, however, would be easily accomplished by adding  $\text{K}_2\text{SO}_4$ . If ammonia was desired, taking into account the statement by Mond, one would declare for  $\text{BaO}$  as, owing to its relative infusibility and non-volatility, it is specially suited to regeneration. I think, however, we should not overlook the claims of ammonia as a base, as it possesses important advantages over the others. If it is a fact that  $\text{NH}_4\text{CN}$  can be easily produced by passing  $\text{NH}_3$  over heated charcoal, as has been stated by several chemists, it seems to be of great importance, because we have here a base which has no action on the retort, and as neither it nor the  $\text{NH}_4\text{CN}$ , seeing they are both volatile, are retained by the charcoal no lixiviation would be required. As regards the conversion of the  $\text{NH}_4\text{CN}$  into  $\text{KCN}$  this could be accomplished by passing the former as it issued from the retort through a hot concentrated solution of  $\text{KHO}$ , whereby the  $\text{NH}_3$  would be set free, and could be returned to the retort to be again converted into cyanide. One great point in having a volatile base is, that as the products of the reaction are formed they are removed out of the sphere of action, and so the reaction is allowed to go on without interruption. Pressure, if it could be applied, would no doubt help this process to a satisfactory conclusion.

It seems to be a question of apparatus more than a modification of any of the processes named which will help to solve the problem, and it seems as if fireclay retorts of not too large dimensions, heated very strongly, would be required, and the nitrogen will have to be almost free from other gases. Considerable attention is being devoted to the question at present, and any experience that I have gained is at the disposal of anyone interested in the matter. (See also pages 61—64.)

The discussion was postponed until March 4th.

## THE SALT DEPOSITS OF KHEWRA, IN THE PUNJAB.

BY E. RODGER.

It is well known that the Indian Government derives a considerable revenue from the duty upon salt, amounting to about 6,000,000*l.* annually, and with a view to the correct realisation of this income, exercises a jealous supervision over all the sources for the supply of this substance. These sources of supply are various. Large quantities of salt are imported into India from this country, a considerable amount is obtained from sea-water by means of evaporation by solar heat, and similar means are used to prepare it from the waters of salt lakes, notably the Sambhur Lake, near Jeypore, in the Rajputana district, and, lastly, there are, in the north-west corner of the Punjab, the extensive deposits of rock salt which are the subject of this paper. The

deposits are situated in the Salt Range, a chain of hills which may be considered as one of the spurs of the Himalaya mountains, although hardly connected directly with them, and the mines are not very far from the battlefield of Chillianwallah. There is now a railway which runs up almost to the entrance of the mine, by means of which Khewra can be reached in about 12 hours from Lahore.

The hills referred to, which seem to be singularly barren, rise boldly and abruptly from a level alluvial plain, through which flows, at no great distance from the base of the mountains, the river Jhelum, one of the tributaries of the Indus. Khewra itself is a small village, built well up the hillside, depending entirely on the salt mines for its existence, and almost entirely inhabited by the miners and their dependents.

One mine only is being wrought at present; it is a very extensive one, called the Mayo mine, which name was bestowed on it in memory of a visit paid by Lord Mayo during his tenure of office as Governor-General.

So far as I could judge, the mine seems to be very economically worked, except as regards the small salt, to which, however, I will refer later.

The manner of working is as follows:—

On the salt being reached, which is done by driving a tunnel for a short distance horizontally into the hillside, a chamber is cut in the salt, 45 ft. deep, from front to back, of a convenient height and length (varying in the early stages with the height and width of the salt deposit). Then a wall of the solid salt, 25 ft. thick, is left standing, with only a 12-ft. gallery running through it, and another 45-ft. chamber is commenced beyond. The wall of salt is left, of course, to support the roof. The workings are carried on at various levels, for the salt runs in layers for 900 ft. above the lowest level at which it is worked, that is to say, above the level of the lowest entrance to the mine. It is arranged that the chambers in the various levels shall coincide with one another, and thus it happens that when one chamber is worked out, another is commenced directly above it, and, being worked downwards, in time the two form only one chamber, but of double the usual height, and in some cases more than two chambers are thus run into one.

Some of the chambers formed by this process are 180 ft. high and 45 ft. broad; one which I saw was so high that blue lights burned below totally failed to illuminate the upper part at all, and, to show the height, a small fire-balloon was made use of. When I say that there are upwards of 20 chambers open, several of them as large as this, besides all the galleries and small cuttings, some idea may be formed of the vast amount of salt which has been removed, and this without doing more than touching the outskirts of the deposit.

About 1,200 labourers are employed in all, and they average about eight annas a day of wages on piece work. The workers are all Mahomedans, and they have a number of curious customs, one being that they work only nine months in the year, the remaining three being spent among the higher hills in holiday making.

The salt is blasted out by means of powder and the lumps are then cleaned if need be, and are afterwards broken to a convenient size.

The tools used are few and simple. A long iron bar or "jumper" for boring the blast-hole (which the miners do by thrusting the bar with both hands, not by striking it with a hammer as we would do), a small hammer for loosening the jumper when it jams, and a scraper for clearing away the powdered salt from the hole, the small dust thus obtained being used for tamping.

A tramway runs through the principal galleries of the mine; it is worked by coolies, who are found to be more economical than mechanical haulage, and large numbers of women are employed as porters to carry the salt from the working spots to the loading stations on the tramway lines. As is usual in subterranean workings the temperature of the mine is very constant, warm in winter and cool in summer. At the time of my visit, in the month of February, the thermometer was about 86° F. inside the mine, and I am told that this temperature is hardly ever much exceeded, so that during the hot weather the officials retire into the mine for the sake of coolness while doing office work, which at other times is done above ground.

The small salt to which I referred in the beginning of the paper consists of the small splinters and fragments produced by the blasting and by the trimming the lumps; it is unsaleable they say, and is used to fill up old workings and prevent collapse. This seems at first sight to be a great waste, but if these disused chambers must be filled up, perhaps this small salt is the cheapest material at hand.

The deposit of salt runs much deeper than they work, as it is not considered advisable to work below the level of the plain; first, on account of water, and secondly, to avoid the extra labour of carrying the salt up to the outer level. The deposit is exceedingly compact and solid, exhibiting very few cavities or fissures, and the mine, therefore, lacks the picturesqueness of some of those salt deposits in which these abound. So far as I know, only one cavity of any size has been found, which, like most similar ones in other salt mines, is partially filled with brine, and has the roof covered with crystals, but it is only of small extent.

I did not see any analyses of the salt, but the superintendent of the mine informed me that the best samples contained about 99 per cent. of chloride of sodium and 1 per cent. of all impurity, including water and insoluble matter, while the worst contained about 96·4 per cent. of chloride of sodium and 3·6 per cent. of impurity, mostly insoluble matter. I may here mention that fine crystals are rare, and that when extracted the mineral is of a pale pinky red hue, when viewed in large masses, when finely ground it is as white as snow. The duty upon salt at the time of my visit was Rs. 2·8 per maund (1 maund equals 82½ lb. nearly), while the cost of the salt itself at the mine is a mere trifle. I need, therefore, hardly point out that smuggling salt would be a very profitable business, and therefore, to prevent any contraband traffic, the mine and its approaches are heedfully guarded by watchmen, and a number of means are used to prevent pilfering, &c.; but these precautions need only be alluded to in passing.

When removed from the mine, the salt is stored in a store near the railway station, to which a siding runs. The salt is packed in bags, and transported in closed trucks, the doors of which are locked, to prevent the contents being tampered with.

In conclusion, I may say that these mines have been worked for many years, how long is uncertain, but they have been a monopoly of the Indian Government since the annexation of the Punjab in 1849, and for long before that date were worked by the Sikhs.

Lastly, I wish to take this opportunity of recording my indebtedness to the courteous superintendent of the mines for the kindness with which he received me, an unexpected visitor, at an awkward time, and for the care which he took that I should be shown everything of interest.

#### DISCUSSION.

The CHAIRMAN said he observed from Mr. Rodger's description of the mines that the method of working them was much the same as employed at Stassfurt. He observed also that, as at Stassfurt, the salt was of a pinkish colour, and it would be interesting to know from what that colour arose. At Stassfurt it was caused by crystals of peroxide of iron, which formed beautiful objects under the microscope. It would have been a benefit if Mr. Rodgers had brought samples home with him, so that some of our more enterprising members might have had the opportunity of examining them, particularly as to the presence of bromine and potash salt.

Mr. RODGER, in reply, said he had no opportunity of ascertaining whether bromine and potash were present or not, as they could readily understand when they considered in what an out-of-the-way part of the world the mines were situated. There chemical analysis was not brought to any degree of perfection, as the salt was looked upon only as an article of food. Regarding the presence of peroxide of iron, he had no doubt but such did exist, but whether or not it was in crystals he could not say. In reply to a query as to whether the mines were situated far from the sea, he stated that Karachi was the nearest port, which would be distant, he thought, from 800 to 1,000 miles.

## THE QUANTITATIVE ESTIMATION OF COLOURING MATTERS BY MEANS OF THEIR ABSORPTION SPECTRA.

BY T. L. PATTERSON, F.I.C., F.C.S.

PERHAPS there is no property so characteristic of an elementary body as that observed when the light which it emits in a state of incandescence, is examined under proper conditions by means of the prism. The smallness of the portions of matter required to be operated on, the delicacy of the reactions, and the definiteness of the results, all tend to make prismatic analysis a most exact branch of physical science and a very attractive study.

The same cannot be said of absorption spectroscopy. Here we have no lines whose position can be measured with exactitude, except in one or two instances. Neither can we operate on such minute quantities of matter. Nor is the range of bodies great which can be examined in this way. Only coloured bodies, as a rule, are available; and of these only those which absorb light selectively. There are, however, a goodly number still left which we may turn to practical account; and it is to some of these and the method of their determination that I ask your attention to-night.

Several attempts have been made to estimate colouring matters by means of their absorption spectra. So far as I have been able to ascertain, Viorordt\* in 1871 was the first to arrange apparatus for this purpose. His method consisted in the use of two slits—evidently in line—in front of an ordinary spectroscope, one for a standard solution of the colouring matter under observation, the other for one of unknown strength. By adjusting and measuring the width of each slit by means of a micrometer screw where absorption in the two solutions was equal, he was able to calculate the strength of the unknown one.

Hugo Schiff, in the same year,† proposed to estimate the colouring matter in aniline salts and blood, &c. by diluting a strong solution of known strength until a certain thickness had the same intensity of absorption when examined by an ordinary spectroscope as a similar thickness of the solution of unknown strength. By observing the amount of dilution the colouring matter was readily ascertained.

In 1874 Hemmig‡ used the absorption spectra obtained when light of equal intensity was passed through two columns of coloured liquid. One of these was a weak solution of known strength, gradually augmented until the absorption bands were equally intense. From the concentration of the known column and the height of both, he calculated the amount of colouring matter in the unknown one.

H. Krüss§ in 1882 proposed the use of a slit with adjustable sides, by which he estimated the coefficient of absorption for solutions giving band spectra, but I am not familiar with the details of this process. And

G. Krüss|| in 1887 described a universal spectroscope for qualitative and quantitative analysis, of a complicated construction, with two slits in front like Viorordt's, and a slit in the eye-piece for cutting off all but those parts of the spectra under examination. The slits were all controlled by graduated micrometer screws, and the intensity of the absorption bands measured thereby.

As far back as 1873 I devised a method for estimating the amount of colouring matter in solutions which gave band spectra, by adapting a glass tube to the low power objective of a microscope, which worked vertically in a larger tube fitted to the sub-stage. On examining the light, transmitted through a coloured solution placed in the lower tube by means of a spectrum eye-piece, having a comparison prism, over which was adjusted a sealed tube containing the standard solution, I was able to determine the height of a column of liquid of known strength, which gave the same band absorption as the tube over the comparison prism.

The height of the column of liquid was adjusted by means of the sub-stage pinion, the head of which was graduated for the purpose. On now placing another solution of unknown percentage, but known strength, in the sub-stage tube, and adjusting the height of the column to give the same absorption as before, the two spectra being viewed alongside each other in the eye-piece, it was easy to calculate the value of the unknown one. The quantity of colouring matter being the same in each column, the relative proportions were inversely as their heights, as in an ordinary colorimetric estimation.

I used this apparatus occasionally and got fairly good results, but the method is tedious and requires very careful adjustment of the light, and all the parts of the instrument. The body of the microscope must not be moved during an observation, or if so, it must be brought back to the same position it occupied before disturbance, otherwise the intensity of the light—varying as it does inversely as the square of the distance—would make some difference in the results. By moving the sub-stage in the path of the ray this error is avoided. Observations are made by setting the sub-stage milled head to the zero mark, and lowering the body till the tube on the object glass touches the bottom of the sub-stage tube. On turning down the sub-stage the liquid flows in by displacement and can be regulated to the proper height by noticing the coincidence of the bands in the eye-piece. Besides the care required in making an observation, another difficulty presents itself; for the separate comparison of two columns of liquid against a standard necessitates two readings and consequently doubles the errors.

To avoid these I sought for a better method, and hit upon the idea of adapting a slit and spectrum eye-piece to a suitable colorimeter. The only one I know of which lends itself to this kind of work is that made by Laurent, of Paris. In this instrument two tubes with flat bottoms for holding the solutions to be examined are supported side by side on suitable clips or brackets. Two narrow cylindrical tubes with flat ends are arranged to move vertically in the larger tubes, by means of rack and pinion on the sides of the instrument, with a range of 50 mm. graduated to half a mm. Over each tube a glass prism is placed, which reflects the light transmitted from a plane mirror beneath into an eye-piece, in which the two rays are focussed as semi-disks in one plane. Colorimetric measurements are easily made with this instrument, and the readings are very close.

I found considerable difficulty getting a spectrum eye-piece fitted to the colorimeter. On taking it to a well-known spectroscope maker in London he told me it was impossible, and would have nothing to do with it. Mr. Hilger fitted an eye-piece but it did not suit. Ultimately I got Mr. White, of Glasgow, to fit an adjustable slit just over the reflecting prisms; and adapted the prismatic eye-piece of a micro-spectroscope myself, with the result that I now have an instrument which works perfectly. I mention these difficulties, not because they are of any consequence now, but to point out that one should not be discouraged because an optician cannot comprehend the principle involved in adapting a particular piece of apparatus to a special end. He must work it out for himself.

The slit opens out wide, and, as now designed, the instrument may be used with the eye-piece suited for each, either for colorimetric or spectroscopic work—qualitative or quantitative.

In using the instrument, light reflected from the mirror beneath passes axially up through the solutions in the two tubes and moveable columns, where it is received on the plane faces of two prisms cut so as to totally reflect the light twice at right angles. Both beams now pass the slit in a divided slice of light—so to speak—which is analysed by a direct vision spectrum eye-piece, in which two spectra of equal intensity are seen. Gas or lamp light is better for this work than daylight, because it has no absorption lines to interfere with the bands; and the less refrangible end of the spectrum is brighter than with any but direct solar light. It is better to use a screen, as shown in the sketch, to shade extraneous light off the eyes. A little micrometer is adapted to the eye-piece by which the bands or lines can be measured

or mapped. Of course the Fraunhofer and bright line spectra can be examined as well with this instrument as with any other, but the dispersion being necessarily small it is not possible to measure the lines with any degree of accuracy. This spectroscope is properly adjusted for work and ready for use when the slit has a proper width, and the two spectra are seen in the eye-piece to have an equal intensity; and when the index of each cylindrical column points to zero on the scales, with the base of the columns just touching the bottoms of the glass tubes.

Fig. 1 is a general view of the spectrum-absorptimeter. Figs. 2 and 3 are front and side views showing the path of light through the instrument. The corresponding parts of each figure are lettered alike.

Fig. 3.

If now a solution of any colouring matter which absorbs light selectively, say a dilute alkaline alcoholic solution of alizarine of known strength, be run gently into one tube from a pipette, the two characteristic bands which this body displays will be seen to come gradually into view, on turning up the milled head of the glass cylinder and allowing the liquid to flow in between the base and the bottom of the glass tube. By raising or lowering the cylinder it is easy to get the exact thickness of liquid at which the bands are seen to the best advantage. If another solution of alizarine of unknown strength—it may be more or less concentrated—be run into the other tube, and the milled head turned so as to raise the glass column, a point is easily reached at which the two spectra viewed in the eye-piece are seen to be equal. On reading off the heights of the two columns, the strength of the unknown one is found to be inversely proportional to the height of the columns and the strength of the known solution. Let the height of the standard column be  $a$ , and its strength  $b$ , the height of the unknown column  $c$ , and its strength  $x$ . Then  $x$  is found by the formula  $\frac{a b}{c} = x$ .

I have said it is easy to get the exact thickness of liquid at which the bands are seen to the best advantage. This requires some explanation. It is not advisable when making comparisons to work with the bands black or even very dark. They should possess a somewhat smoky colour, if I may so speak, which is a dark shadow rather than a black bar; and not absorb all the light from that part of the spectrum in which they appear. The most characteristic band should always be used when there are more than one; and it is advisable in most cases to use a wide slit above the prisms to shut out all portions of the spectra except that under observation. Only in this way is it possible for the eye to judge of the shades of intensity obtained by movements of the milled head, and find the point of adjustment where no difference can be observed between the bands in the two spectra.

With these precautions a number of readings are fairly close and may be compared with those obtained with a colorimeter. But the accuracy depends to a large extent on the sharpness of vision in the observer, and a little acquaintance with the instrument. With small percentages

13. Alizarin.

great accuracy may be obtained, whilst with large percentages the readings will be less truthful, but the process is not intended for such unless in exceptional circumstances.

I have made a number of experiments to test the accuracy of reading, and illustrate the method of work.

Olive oil gives a well defined band in the red end of the spectrum No. 1, which is suitable for testing the closeness of independent readings. A series of readings were made with the same specimen of oil in both tubes of the instrument. When the left-hand column was 8 mm. high, a suitable absorption band was obtained for making the observations. The right-hand column was then altered and adjusted until absorption in the two spectra appeared to be equal. The following are the readings of the right column the left remaining stationary at 8 mm.

	Mm.
1st.....	8
2nd.....	7.75
3rd.....	8.50
4th.....	8.25
5th.....	7.50
6th.....	8.25
7th.....	7.75
8th.....	8.00
9th.....	7.50
10th.....	8.50

The mean of these is 8 mm. with an error of  $\pm 0.5$  mm.  $\pm$

Solutions of magenta in alcohol give a broad band of absorption in the green part of the spectrum No. 12, not very suitable for this kind of work, because broad bands are not so easily compared as narrow ones; but I have chosen magenta to show the amount of error to be expected in some cases.

A stock solution of this colouring matter was prepared containing .012 grm. in 400 cc. of alcohol = .00003 grm. per cc. A column of about 1.25 mm. was all that was required of this solution to give a suitable band for examination, but this column is too short for close comparative work; therefore 5 cc. were diluted to 100 cc. with alcohol and used as a standard in the following experiments.

Four solutions, *a*, *b*, *c*, and *d*, were made containing respectively 20, 10, 4, and 3 cc. of stock solution in 100 cc. of alcohol. Each were examined separately against a column of the standard solution, and five readings were taken of each solution when the absorption in the two spectra appeared equal, after re-adjusting for each reading.

*a*. The readings for this solution were 8, 7.5, 7.5, 7.25, and 8, the mean of which is 7.65 mm. when the standard column stood at 30 mm. Calculated from the strength of the solution the reading should have been 7.5 mm.

*b*. The readings were 14.75, 14.5, 15, 14.75, and 15.1, mean 14.8 mm., against a standard column of 30 mm., and the calculated height is 15 mm.

*c*. Read 38, 37.25, 37, 37.5, and 37.1, mean 37.37 mm., when the standard column stood at 30 mm., the calculated height being 37.5 mm. And

*d*. Read 42, 42, 41.5, 41, and 40, mean 41.5 mm., when the standard measured 25 mm. The true height should have been 41.66 mm.

Aniline green gives a well-defined band in the red No. 11, somewhat like chlorophyll, but more refrangible. A series of experiments were made with this colouring matter in the same manner as with magenta. The weight dissolved was the same, as also was the solvent and the dilutions; therefore I need not repeat them here.

*a*. When the standard column measured 33 mm. the readings with this solution were 7.6, 7.25, 7.5, 7.5, and 7.25, mean 7.42 mm. Corrected for strength, the height should be 7.5 mm.

*b*. With the standard column at 25 mm., read 12.1, 12.5, 12.5, 12.6, and 12.1, mean 12.36 mm., instead of the calculated height of 12.5 mm.

*c*. Against the standard at 25 mm. read 32, 31.5, 30, 29.75, and 32, mean 31.05 mm. instead of 31.25 mm. And

*d*. With standard at 20 mm. read 33.25, 33.5, 33, 33, and 33, mean 33.15 instead of 33.33 mm.

Tabulating these results and calculating them to 100, we find the error in reading to be as follows:—

TABLE NO. 1.—MAGENTA SOLUTION.

—	Calculated Height of Column.	Mean Height of Five Readings.	Colouring Matter found.	Error due to Reading.
	Mm.	Mm.	Per Cent.	
a	7.50	7.65	98.04	— 1.96
b	15.00	14.80	101.36	+ 1.36
c	37.50	37.37	100.35	+ .35
d	41.66	41.50	100.39	+ .39

TABLE NO. 2.—ANILINE GREEN.

a	7.50	7.42	101.08	+ 1.08
b	12.50	12.36	101.13	+ 1.13
c	31.25	31.05	100.64	+ .64
d	33.33	33.15	100.54	+ .54

The eye-piece slit was used with the green solutions, but not with magenta, as, in the latter case, better results were got without it. The errors recorded are less with dilute than with strong solutions, but none are excessive when we consider that this is the most trying method of testing a process which is only intended for estimating small percentages of colouring matter. It would be easy to multiply such experiments, but those I have given will suffice to show the error of reading and the minute quantity of

colouring matter required to make a quantitative estimation. The *d* solutions contain only  $\frac{.00009}{100.000}$  of a gram. per 100 cc., and much less would be required if the solutions were concentrated.

In the experiments just detailed, I have dealt with simple colouring matters; but when the absorption bands occur in different parts of the spectrum, there is no reason why two, or even more, should not be determined in the same solution. By way of illustration I will mention the results of some experiments with mixtures of solutions of the two colouring matters—magenta and aniline green—we have been considering. Known quantities of these were mixed in varying proportions, thus—

I.—Contained 3 cc. stock solution of magenta and 20 cc. stock solution of aniline green in 100 cc. alcohol.

II.—5 cc. magenta to 20 cc. green.

III.—10 cc. " 20 cc. "

IV.—20 cc. " 20 cc. "

V.—10 cc. " 10 cc. "

VI.—20 cc. " 10 cc. "

VII.—20 cc. " 5 cc. "

VIII.—20 cc. " 3 cc. "

all made up to 100 cc. with alcohol.

I need not record the various spectroscopic readings. It will be sufficient to say that the mean of 5 were taken in each estimation, against the same simple standards as were used in the previous experiments. The errors were small with aniline green, but larger with magenta, especially in the strongest solutions. Calculating the cc. of colouring matter in 100 cc. of alcohol in each experiment, to 100 of mixed colouring matter, and recording the result of the readings in percentages, the errors are brought into relief. This has been done in the following table.

Table No. 3, showing the percentage of magenta and aniline green, found in mixtures of these colouring matters:—

TABLE NO. 3.

Number of Experiment.	Magenta.			Aniline Green.		
	Calculated.	Found.	Error.	Calculated.	Found.	Error.
	Per Cent.	Per Cent.		Per Cent.	Per Cent.	
I. ....	13.04	13.51	+ 0.47	86.96	87.24	+ 0.28
II. ....	20.00	19.42	— 0.58	80.00	78.74	— 1.26
III. ....	33.33	32.42	— 0.91	66.66	64.10	— 2.56
IV. ....	50.00	48.87	— 1.13	50.00	49.75	— 0.25
V. ....	50.00	40.66	— 0.34	50.00	49.70	— 0.30
VI. ....	66.66	63.54	— 3.12	33.33	33.11	— 0.22
VII. ....	80.00	77.00	— 3.00	20.00	19.83	— 0.17
VIII. ....	86.96	83.79	— 3.26	13.04	12.94	— 0.10

Experiment V. was made with half the colouring matters present in No. IV. solution. The magenta estimation is very near the truth, but I consider it doubtful in the absence of other experiments. A careful examination of Table 3 reveals a tendency to over-estimate the height of the working column, giving a — error in every determination except the first. The high percentages are not closely estimated especially in the case of magenta. But from 50 per cent. down the — error has a ratio decreasing with the percentage of colouring matter, confirming what I have already said, that better results are obtained with small percentages. The decreasing ratio and close reading are very marked in the estimation of aniline green. A slight general absorption of the whole spectrum takes place with two colouring matters in the same solution, which under certain circumstances abnormally darkens the band under examination; but it did not affect these estimations. Green, for instance, darkens the total spectrum a little, but where it was present in largest quantity, as in experiments I. and II., the error in the magenta estimation was least, and *vice versa*.

Turning now in another direction, let me cite a few examples illustrating the application of this method of analysis to ordinary quantitative work.

The estimation of alizarin in alizarin paste is an operation which involves a considerable amount of time and manipulative skill in precipitation, filtration, and washing. Considerable difficulty, too, is experienced in getting rid of associated colouring matters. With the spectroscope the quantitative estimation is as easily performed as is that of aniline green or magenta, and the foreign colouring matters interfere very little with the observations. Three samples of alizarin paste were examined in this way; .025 grm. of each was dissolved in alcohol and rendered alkaline with a sufficiency of alcoholic potash to give the characteristic absorption No. 13, and made up with alcohol to 100 cc. For comparison, a specimen of pure alizarin was prepared by sublimation from alizarin paste, after solution in caustic soda, precipitation with  $\text{BaCl}_2$ , and washing, followed by decomposition with  $\text{HCl}$  and washing, &c. A standard solution of the pure sublimate was then made containing .004 per cent. of alizarin. On comparing these solutions in

the spectrum absorptimeter—to give the instrument a name—and calculating the results from the mean of five readings which closely agreed, the first was found to contain 5.33 per cent. alizarin, the second 7.69 per cent. alizarin, and the third 23.36 per cent. alizarin. Of course all here depends on the purity of the standard specimen, and every effort should be made to secure it. I do not say mine is absolutely free from impurity, having only been made for the purpose of this illustration; but so far as it is pure the results are very close to the truth. The first sample is said to be 7 per cent. and the second 10 per cent. Both are very old specimens. The third was in the condition of putty, and has, I may mention, a somewhat curious history. It came from Germany in a lot of beetroot sugar, and passed the samplers unnoticed until the sugar was being melted in the refinery. The alkalinity of the sugar developing the purple colour of the alizarin and dyeing the men's hands was the occasion of drawing attention to it. On examination it was found that the sugar had been filled into bags which had been previously used for packing alizarin paste. The insides of the bags were smeared with alizarin, and some of them contained masses of 20 or 30 lb. of that colouring matter. Altogether between 3 and 4 cwt. were recovered from that lot of sugar. I should add that I am inclined to believe the presence of alizarin in this connexion accidental, although the cause of it was never satisfactorily ascertained.

A piece of Turkey-red cloth weighing .963 grm. and measuring 24 square inches was treated with concentrated sulphuric acid, and the colouring matter precipitated with water, filtered, and washed. The alizarin on the filter was dissolved in alcohol and alcoholic potash and made up to 200 cc. On comparing this solution with the standard mentioned in the previous experiments, and figuring out the result, it was found that the cloth contained 0.83 per cent. alizarin and 0.4306 grm. per yard.

The colouring matters in sweetmeats, which are now so attractive and various, can be determined in this way—that is to say, those of them that have absorption spectra. The spectra of known colouring matters, of the same or similar tint, are compared with that of the sweet under examination until one is found to correspond. The amount is then easily ascertained. One example will suffice here.

Twenty grms. of a pink tablet were dissolved in alcohol. The solution gave two bands in the blue which exactly coincided with those exhibited by an alcoholic solution of V E eosin No. 9. When compared with a solution containing 0.001 per cent. of this colouring matter the tablet was found to contain 0.00294 per cent. This is a very small, and no doubt harmless quantity, yet it was easily recognised and estimated. The eosin family seem to be largely used for this purpose.

Many of the coloured gelatin films used in confectionery give absorption spectra by which the colouring matters can be identified. I have found aniline greens and blues, magenta and eosin pinks, some of which fluoresce in the film almost as much as they do in solution. One grm. of a flesh-coloured specimen was dissolved in 400 cc. equal parts water and alcohol. The spectrum agreed with that of V E eosin, and revealed the presence of .162 per cent. of this colouring matter when compared with a standard solution containing .001 per cent. dissolved in water and alcohol. A purple film treated in the same way yielded .66 per cent. of magenta.

A paraffin candle was found to be coloured with erythrosine R E; No. 10 spectrum. Five grms. were dissolved in gasoline, and shaken up with alcohol in a separator. The colouring matter was thus transferred to the alcohol. After removal the coloured solution was made up to 100 cc. with the washings from the gasoline, and compared with a standard containing .001 per cent. of erythrosine. Twenty mm. of the standard equalled 9.38 mm. of the candle solution, indicating .043 per cent. of erythrosine.

Sometimes a coloured impurity may be turned to account for the quantitative estimation of the substance in which it naturally exists, and although not always present in exactly the same proportion, it can give some definite information which may lead to useful results. The analysis of oils is a case in point. I have often found the spectrum absorptimeter useful in approximately determining the amount of

adulteration where certain vegetable oils were mixed with those of animal origin. Chlorophyll is of course the colouring matter which enables us to recognise the mixture. It is always present in certain unrefined vegetable oils as an impurity, and its quantity is fairly constant in fresh specimens of the oil. One glance at an oil with a pocket spectroscope is sufficient to reveal the absorption bands when they exist; and the quantity of the oil giving them can afterwards be determined in the absorptimeter. The spectra of oils giving chlorophyll bands have often been referred to and mapped, but I am not aware that any attempt has hitherto been made to utilise the bands for quantitative work. Unfortunately chlorophyll is not always stable. The bands are often eliminated by refining and long exposure to light, especially those in the more refrangible end of the spectrum. Hence fresh samples should always be used for comparison, and when kept for any time, should be preserved in the dark. The band in the red is well defined\* and very characteristic. The other three are all more or less faint and only seen in good fresh specimens. The intensity of chlorophyll absorption in hemp-seed, brown rape-seed, green rape-seed, linseed and olive oil is in the order just named; and the bands have the same width and position for an equal intensity. Their spectra are shown in the diagrams, Nos. 1 and 3—6. Green olive oil differs from the others in this, that it has only two absorption bands, one of them very faint, and these are more refrangible as seen at No. 2. In linseed and olive oil the secondary bands are very faint, and seldom met with. It is therefore comparatively easy to distinguish green and yellow olive and linseed oil from others of the band-giving class. When the oil in a mixture is not one of these or when there is any doubt, it may be recognised by chemical tests and its quantity found by the absorptimeter. It is a good plan to map the absorption spectra of oils which give them on sectional paper for reference, so that when a mixed sample turns up, it can be seen by means of the eye-piece scale which of the oils already mapped the mixed specimen must be compared with. The comparative estimation should not be made unless the bands in the two spectra occupy the same position, and can be brought to the same intensity.

The most common adulteration of this kind which I have noticed is that of mixing linseed with fish oils. But olive and rape are also mixed with these and other oils. Whale, seal, and porpoise oil are all mixed with linseed in varying proportions, and no one whom I have asked seems to know the reason why; indeed, the oil merchants pretend to be totally ignorant of the mixture. Unless whales and other fish have become vegetarians and store up chlorophyll in their fat cells, there must be some manufacturing reason for chlorophyll bands appearing so often in oils of this class. Perhaps the price of vegetable oils, which is usually above that of fish oils, puts them out of the category of adulterants into that of improvers; for their addition undoubtedly brings up the colour of dark fish oils, gives them more body, and reduces their smell. But this only removes them from one category to another, and is no justification for the mixture. Whether the soap boiler, the jute manufacturer, and the leather dresser, who use fish oils in large quantity, are prepared to homologate this practice, I cannot pretend to say, but it is worthy of their consideration because of the extent to which it is carried.

Take the following examples:—

1. A sample of whale oil gave a strong band of absorption in the red corresponding with the band in linseed oil. On comparing these two oils in the instrument the height of the whale column was 11.09 mm. (mean of five closely-agreeing readings) against 5 mm. of linseed, indicating  $\frac{5 \times 100}{11.09} = 45.08$  per cent. of linseed oil.

2. Another sample of whale oil absorbed light like green olive, and 15.63 mm. were equal in intensity to 3 mm. of that oil. It therefore contained  $\frac{3 \times 100}{15.63} = 19.19$  per cent. of green olive oil.

3. A sample of seal oil was found to give the linseed spectrum, and 24.13 mm. were found to equal 8 mm.

\* I have some samples which have not lost the *a* band although exposed to light for several years. In dark oils the band is very persistent and alters very little during many years.

linseed, which shows this oil to have contained  $\frac{8 \times 100}{24 \cdot 13} = 33 \cdot 11$  per cent. of linseed oil.

4. *Menhaden Oil*, the product of a small fish very plentiful off the coast of North America, is, I fear, not to be had pure. I have examined three samples and found all mixed with vegetable oil. Two of these were said to be pure, and contained respectively about 14 per cent. and 25 per cent. of linseed oil, whilst in the third, 18·44 per cent. of brown rape oil was present. The presence of rape was confirmed by Valenta's test,\* and the saponification equivalent. The spectrum of this oil, No. 8, is much more intense than that of the darkest pure linseed oil I have seen, and some of the secondary bands are visible. Yet its outward appearance is not different from that of a pure brown fish oil.

5. A sample of lard oil, purchased as pure and genuine, will be the last example. It was found spectroscopically to exhibit the band characteristic of green olive; and when compared with a pure fresh sample at the time of purchase, now upwards of two years ago, indicated the presence of 11·7 per cent. of green olive oil.

As I happen to have this sample of lard oil beside me still, as well as the green olive against which it was tested, I thought it would be instructive to compare them again. The lard oil stood on a shelf in the laboratory, exposed to light all the time, but the olive was carefully protected from light, for testing purposes, by gumming black paper around the bottle. The lard oil was also tested against a fresh sample of green olive of recent date. On making the experiment, the lard oil indicated 8·8 per cent. against the old sample of green olive, and 7·02 per cent. against the new one. The result is very interesting, as it indicates a loss of chlorophyll by the bleaching action of light equal to about 4·68 per cent. of the olive oil originally found in the lard, whilst the olive oil protected from light may be said to have lost little or nothing of its chlorophyll during two years. 1·78 per cent., the difference between the last two estimations, may be due as much to difference of sample as to loss of chlorophyll. The experiment illustrates what I have said above on the persistency of the *a* band and the action of light on chlorophyll.

In drawing this paper to a close, let me say that I have only referred to a few applications of this instrument and method of analysis; they are chiefly those to which I have had occasion to apply them myself, and others will suggest themselves to every chemist. The colouring matter in cheese and butter can be determined; so also might fuchsine and elderberry juice when present in wines. Some of the impurities in anthracene absorb light selectively, which property might be utilised for their estimation. There are many processes in the arts where fairly accurate results have to be got in the least possible time, where this spectrum method might be found useful; as, for instance, in many dyeing operations. Whilst there are others in ordinary laboratory practice, where the quantity of colouring matter is so minute and difficult to separate and weigh, that this method of determination will be preferred to a gravimetric one.

In conclusion, I beg to acknowledge the valuable assistance of my friend Mr. John McGlashan, who has made all the experiments in connexion with this paper. I have also to thank Mr. Hugh Lusk for preparing the diagrams, and several friends who kindly procured for me pure samples of oils.

#### DISCUSSION.

The CHAIRMAN said that Mr. Patterson, with his characteristic ingenuity and perseverance, had overcome what was the first step to a solution of the difficulty which lay in the way of the determination of colouring matters by means of their absorption spectra. A great deal had been said as well as written on this subject, but he had never before found anything entirely conclusive so far as quantitative determinations were concerned. He was, however, now satisfied that, with the ingenious arrangement which Mr. Patterson had explained, a new and powerful instrument had been

brought into the hands of chemists. He was quite unprepared for the accuracy of the results obtained with small quantities, and even with the larger proportions of colouring matter which Mr. Patterson had shown, and he was also gratified at the great utility which seemed to be in prospect for that branch of work. It would scarcely be credited by those who were not involved in commercial questions relating to colouring matters how much trouble and disagreement there existed with regard to the estimation of mixed colouring matters. For example, a railway company contracts for a large quantity of "cochineal lake," and of course stipulates that it shall contain no other colouring matter. That particular colour had become a very favourite one for passenger carriages, and as it had to stand the sun and weather it was necessary that it should be of an unalterable character. It was a very common practice, however, to introduce other colouring matters, such as "eosines," and the result was that the colour of the railway carriages, after being exposed to the sun for a short time, faded. He had had a case of this kind before him quite recently.

There were so many applications for which the process would be serviceable that he believed it would materially aid in opening up a new branch of analysis altogether. The estimation of the proportions of some of the coal-tar colours which were used for colouring sweetmeats was a very important one. He had found some of these colours in confections lately, but the idea of determining accurately the proportion was not entertained, for the want of reliable methods.

One particularly interesting branch of this investigation was that relating to oils. He did not know whether oils were more adulterated now than formerly, but it was a fact every second sample that came into his hands was adulterated. He was glad to think that the comparative examination of the chlorophyll absorption bands gave every hope of serving not only to distinguish some particular kinds of vegetable oils, but of determining their proportions. Mr. Patterson suggested that there was a difficulty in accounting for the presence of these higher-priced vegetable oils in commercial fish oils, which were generally very cheap. They were no doubt introduced more to improve the appearance than to cheapen the article. The argument was often brought forward in practice and in courts of law, that it was quite impossible such vegetable oils could be present, for they were more expensive than the oil with which they were mixed. The only other reason he could assign for such adulteration was that a merchant sometimes got a job lot of these vegetable oils very cheaply, perhaps at a bankrupt sale or under special circumstances, was at a loss to obtain a suitable outlet for it, and so found it convenient to mix them with another, although ordinarily a cheaper oil. But the chemist had nothing to do with that. All he had to do was to make sure that his methods of analysis were unimpeachable, and his practice correct; then he would almost invariably find that these anomalies were explicable through the existence of special conditions or circumstances.

Mr. BIGGART asked if the presence of cotton-seed oil in lard could be detected by Mr. Patterson's process.

Mr. ELLIS asked how two colouring matters, where the bands happened to overlap each other, could be determined.

Mr. PATTERSON, in reply to Mr. Biggart, said that his process could not be applied to cotton-seed oil because it gave no absorption spectrum. It could be applied only to those oils he had mentioned, with a few others of which he had not got samples, and he would just like to mention that too much confidence was not to be placed on his or any other process. With reference to Mr. Ellis's question, in such a case the colouring matters could not be determined together. They would require to be separated, if possible by treatment with different solvents, or in other ways.

PROFESSOR CRUM BROWN, D.S.C., F.R.S., IN THE CHAIR.

## NOTES ON THE ALKALOIDS.

BY D. R. DOTT, F.R.S.E.

THERE exists considerable diversity of definition of the term alkaloid, which is indeed regarded by Professor Armstrong as indefinable. The author objects to a definition which makes the term apply only to compounds of a markedly poisonous character, or to compounds of a vegetable origin, considering that an alkaloid should be regarded as such on account of its constitution and chemical properties, and without reference to its source or physiological action. It is maintained that an alkaloid is any alkali-like or basic organic compound, whether of the  $NH_3$  or  $NH_2$  type, and that the term is also applicable to the basic compounds in which phosphorus or arsenic takes the place of nitrogen. The views enunciated by Professor Armstrong\* regarding the properties of nitrogen are criticised, the author contending that there is little evidence to show that nitrogen is a substance of great activity in the elementary or atomic as distinguished from the molecular state. A study of the alkaloids does not obviously confirm the theory, as many of these bodies, such as cinchonine and eegonine, are physiologically very feeble substances while on the other hand certain glucosides, like digitalin and strophanthin, are powerfully toxic. Whence it is hardly probable that the toxicity of the poisonous alkaloids is in any direct sense due to their nitrogen.

The remainder of the paper is occupied by some general remarks on the alkaloids and their salts. Although all alkaloids are probably potentially crystalline, some few have obstinately resisted all attempts to crystallise them. Among these is beberine. The author was the first to prepare a crystalline salt of that base, and was enabled to confirm the accuracy of the formula  $C_{15}H_{21}NO_3$ , ascribed by Flückiger from an analysis of the amorphous base. The hydrochloride crystallises in trimetric prisms, which is the form nearly always assumed by alkaloidal muriates. Whence it is probable that many double salts of alkaloids could be prepared, although the double muriate of morphine and codeine is almost the only one which is prepared in practice. The custom (common in this country) of describing salts of the formula  $BHCl$  as hydrochlorates is condemned as erroneous, the expression more probably applying to the so-called chlorates,  $B.HClO_3$ , hydrochloride being the more correct designation of salts of the former formula. Reference is then made to a question of some interest, which has received very little attention. It is well known that while some of the alkaloids are strong bases, whose solutions turn red litmus blue, other members of the class do not affect litmus, and only form well defined salts with the stronger acids. In some cases the combination of acid and base is so feeble that decomposition is caused by water.

It has not been determined which of all the known alkaloids is the strongest. The author tried a series of experiments to determine which of the opium bases is the strongest, by treating equivalent weights of two of them with an equivalent of hydrochloric acid in presence of water; and also, in some instances, by digesting a molecular weight of one salt in solution with a molecular weight of another alkaloid. Conclusive results are not always obtained. Codeine is the strongest and narcotine or narceine the weakest. Though doubtless the point is principally determined by the relation which the nitrogen bears to other groups in the molecule, it appears that the solubility of the base is also a factor in the case. For instance, codeine is far more soluble both in water and in alcohol than is morphine, so that the former is in a more favourable position for combining with the acid. In the case of an alkaloid which forms two or more hydrochlorides, there cannot

as a rule be any difficulty in determining which of the salts is the normal. In the case of the cinchona alkaloids, however, which contain two nitrogen atoms of different value in the molecule, and form two platonic salts, the question is not so simple, hence in some books the ordinary quinine sulphate  $Q_2.H_2SO_4$  is described as the basic, in others as the normal salt. It is a matter of old observation that several of the organic bases when precipitated by caustic alkali dissolve in excess, though it was not till a few years ago that Chastaing proved that this is due to the formation of definite compounds of the alkali and alkaloid. He regarded morphine as resembling phenol in so far as it contains a hydroxyl atom which readily allows its hydrogen to be replaced. This having been shown to be the case in regard to morphine, it became interesting to know whether other alkaloids which are readily soluble in alkalis contain a similar hydroxyl group. With this view the author and Stockman† experimented in narceine, but did not succeed in replacing a hydrogen by a methyl or ethyl group, by the method which easily effects the desired change on morphine.

In conclusion, reference is made to the alkaloids of the ammonium as distinguished from the ammonia type, it being considered that the former class have not received all the attention they deserve. This probably arises from the fact that they have a tendency towards a similarity of physiological action. The author approves of the names used by Crum Brown and Fraser,‡ as "methylnorphium iodide" and "ethylstrychnium chloride." The name "morphine methiodide" suggests a compound quite analogous to morphine hydriodide, which is misleading, as the former body does not yield morphine by any method of treatment, but always other products, and possesses also a physiological action quite distinct from that of the morphine salts. When morphine or codeine is heated in a sealed tube with hydrochloric acid, apomorphine is produced, but when the so-called "morphine ethochloride" is similarly treated no apomorphine appears, which is additional proof of the essential dissimilarity of the two classes of compounds. These facts appear to constitute a strong confirmation of the accuracy of the opinion held by Professor Armstrong and others, viz., that the ordinary alkaloidal salts are merely molecular compounds. It seems not unlikely that these ammonium-like alkaloids may become chiefly useful as media for the preparation of new alkaloids, for as methyl-codeium hydroxide yields by heating with an alkali, the potent compound methocodine,§ we may anticipate that an analogous action will occur in other instances.

## Communication.

### DEVELOPMENT OF VOLTAIC ELECTRICITY BY ATMOSPHERIC OXIDATION OF COMBUSTIBLE GASES.

BY LUDWIG MOND, ROME.

THIS Journal, Vol. VIII., No. 12, p. 990, contains an abstract of a note on the above subject by C. R. A. Wright and C. Thompson taken from the Proceedings of the Royal Society, 46, 372—376. In this abstract the following occurs:—

"The battery described by Mond and Langer (this Journal, 1889, 550) is substantially identical in principle with the batteries previously described by Wright and Thompson (Proc. Roy. Soc. 44, 182)." This statement is, in my opinion, incorrect.

On referring to the earlier communications on this subject by Wright and Thompson, including the paper quoted in the abstract (Proc. Roy. Soc. 44, 182) it will be found that none

† Unpublished experiments.

† Pharm. Jour. 1890.

of their previous papers mentions with a single word the construction of a gas battery involving the distinguishing principle of the battery described by Mond and Langer, viz., the use of porous plates impregnated with an electrolyte and coated on both sides with electrodes. The first intimation that Messrs. Wright and Thompson ever made and experimented with such a battery is given in their note communicated to the Royal Society on the 20th June 1889, and it thus becomes evident that they have not previously described a battery "substantially identical in principle" with Mond and Langer's. The best proof, however, of how far Messrs. Wright and Thompson have been from approaching to Mond and Langer's battery so late as April 1888, the date of their previous communication to the Royal Society, is afforded by the concluding paragraph of that paper, which in summing up the results obtained with the various batteries therein described, states:—

"In no case could any current capable of depositing a few milligrammes of silver per day be obtained with an E.M.F. as great as 1 volt. . . . ."

Batteries similar to those described by Wright and Thompson in their note of June 1889 have been made by Dr. Langer and myself as far back as March 1885, but it has taken us until February 1888, the date of a patent specification giving a full and detailed description of the battery in its present form, to perfect our invention—a fact which will surprise no one at all conversant with the difficulties of the problem.

## Journal and Patent\* Literature.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

#### PATENTS.

*An Improved Measure and Funnel for Liquids.* T. Brown, Newcastle-on-Tyne. Eng. Pat. 18,259, December 4, 1888. 6d.

THIS is a combined measure and funnel with a spring valve attachment, and is intended for use in measuring liquids. The funnel can be made of any size, and has its sides graduated to any measure required, thus obviating the necessity of first pouring the liquid into a measure. The lower part (or neck) contains a ball-joint and valve, kept in position by a spring attached to a rod extending upwards to the top of the handle, where it is worked by the pressure of the thumb.—E. S.

*Improvements in the Manufacture of Filtering Material, applicable to the Filtration and Purification of Water, Sewage Effluents, Saccharine Juices, Aleoholic Liquors, and other Liquids and Fluids.* H. R. Gregory and G. MacDonald, London. Eng. Pat. 18,177, December 12, 1888. 4d.

THE process consists essentially in reducing ferric oxide by heating it in contact with gaseous fuel. Small pieces of iron ore, preferably hematite, are packed into a retort heated externally, preferably by producer gas. When the

charge is at a cherry-red heat gaseous fuel is admitted into the retort and brought into thorough contact with the ore. At the end of four or five hours if the exit gas be inflammable the process is finished and the charge raked out and allowed to cool. Ordinary coal gas or other gaseous fuel may be used instead of producer gas. The retorts may be oscillated, rocked, raked, &c., by machinery. The magnetic oxide so produced is available for filtering water, sewage, sugar syrups, alcoholic liquors, &c.—J. M. H. M.

*Improvements in Apparatus for Distilling, Evaporating, or Concentrating Liquids.* W. Lawrence, R. C. Garton, and C. H. Garton, London. Eng. Pat. 83, January 2, 1889. 11d.

THIS invention applies to multiple-effect distilling apparatus, in which the vapour raised from the liquid in the first vessel is made use of for heating the partly-heated liquid transferred to the second, that arising from evaporation in the second vessel for heating the liquid transferred to the third, and so on, until all the heat introduced in the original steam is exhausted. Thus the liquid "may pass in succession from vessel to vessel as many times as the columns of liquid in the pipes may, added together, amount to the pressure of the initial steam and liquid in the first vessel." The claims of the patentees principally embrace the construction and arrangement of steam jackets with internal corrugated heating surfaces, pipes, and cylinders of spiral and other shapes, as well as means for causing the liquid under treatment to flow over the heating surface in thin films. There are three sheets of drawings.

—B.

*Improvements in and Apparatus for obtaining Fresh Water from Salt Water.* J. S. Stevenson and H. Stevenson, South Shields. Eng. Pat. 186, January 4, 1889. 8d.

THE object of this invention is to provide means whereby fresh water can be obtained from salt water with fuel, which, together with the apparatus, occupies but a small amount of space, and is of small weight as compared with the amount of fresh water produced. The boiler for evaporating the salt water is heated by liquid fuel (as petroleum), and is preferably made with an internal flue, and return flues, and has a hand-hole with a packing of india-rubber or asbestos, so that cleaning can be readily done. The steam passes into a condenser which consists of an inner pipe with thin walls, and surrounded by a jacket in which cold water circulates. The liquid fuel is stored in a tank, "and kept under a pressure sufficient to maintain a continuous feed against the pressure of the vaporised oil by an air pump, which pumps air into the tank above the level of the liquid." "The liquid under this pressure is then conveyed to burners on the Bunsen principle." The apparatus is especially suitable for use on ships' lifeboats.

—E. S.

*Improvements in Apparatus for Distilling Sea or other Water.* J. Newton, London, and D. A. Quiggin, Liverpool. Eng. Pat. 538, January 11, 1889. 8d.

THIS invention relates to that class of apparatus in which pure water is produced by the distillation of sea or other water, the source of heat being the heat in steam, which may be impure, and is not therefore allowed to mix with the pure water produced in the apparatus. The primary steam, however produced, is admitted into a vertical evaporator, and passing through tubular heating surfaces, preferably helical coils, is condensed and forms impure water which is allowed to flow away. The secondary steam generated in the evaporator passes into other and similar evaporators, and produces pure tertiary steam, which, on its way to the condenser, passes through a feed heater, and heats the feed water which is supplied to the evaporators. For details the specification and drawings must be consulted.—E. S.

\* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Luck, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d. . . . .	1d.
Above 8d., and not exceeding 1s. 6d. . . . .	1d.
" 1s. 6d., " " 2s. 4d. . . . .	1½d.
" 2s. 4d., " " 3s. 4d. . . . .	2d.

*An Improved Composition or Preparation to prevent Incrustation in Steam Boilers.* W. D. Pratt, Nottingham. Eng. Pat. 607, January 12, 1889. 4d.

Irish moss or other gelatinous seaweed is boiled in water to form a glutinous decoction. To this are added "malt culms" and a small quantity of dextrin. These are thoroughly mixed and poured into moulds in the form of blocks, preferably 10 in.  $\times$  10 in.  $\times$  3 in., and dried in a kiln. The proportions of the ingredients vary with the hardness of the water. One pound of the composition to each horse-power of the boiler, or to each 100 gallons of water, is stated to keep the boiler free from incrustation for about six months.

—E. S.

*Improvements in Apparatus for Mixing, Incorporating, or Effecting the Circulation of Liquids and Semi-Liquids in Vessels.* S. B. Boulton, T. B. Haywood, H. E. Boulton, and E. R. Gabbett, London. Eng. Pat. 840, January 16, 1889. 8d.

The patentees produce the circulation of liquid in tanks or cauldrons by rotating therein an upright central shaft to which is secured an inverted conical casing open at both ends and fitted with internal radiating blades, which is entirely immersed in the liquid. Centrifugal action causes the liquid to rise within the casing, thereby drawing fresh liquor from below and discharging at the top. Or the conical casing may be reversed, withdrawing the liquid from the surface and discharging below, the effect being to produce circulation of the liquid in the tank without the use of mechanical stirrers. The specification is accompanied by one sheet of drawings, showing variations in the arrangement and in the shape of the propeller.—B.

*Improvements in or applicable to Edge-Runner Mills for Crushing or Grinding Cement, Ores, and the like.* W. R. Taylor, Rochester. Eng. Pat. 1772, January 31, 1889. 6d.

The patentee directs a blast of air between the grinding surfaces of any comminuting machine, such as an edge-runner, thus removing the finer portions of material, already sufficiently ground, from between those surfaces, so as to aid their action on the coarser particles. A typical apparatus consists of an edge-runner, on the spindle of which, at its lower end, is a bell or inverted cup, whose rim fits into a circular groove in a boss on the bed-plate concentric with the spindle, thus forming a chamber into which air can be forced by a pipe from the lower side of the bed-plate. The air is led away by pipes from the sides of the bell or inverted cup to the rear of the edge-runners, and acts as described above. If desired, scrapers may also be added to loosen the material for the better action of the blast.—B. B.

*An Improved Evaporating and Condensing Apparatus for Producing Fresh Water from Sea-Water or other Fluid for Drinking Purposes and for Boiler Feed.* H. Ferguson, London. Eng. Pat. 11,742, July 23, 1889. 8d.

The object of this invention is "to afford means by which the use of high-pressure steam for evaporating the sea-water in the evaporator can be employed, by which a high duty may be obtained from an apparatus of small weight, and occupying little space." Special arrangements are made for the easy and rapid circulation of the sea-water in the evaporator, and also for the production of dry steam from the same, in order that the water resulting from the condensation of the steam may be practically pure and fresh. For details, the drawings attached to the specification must be consulted.—E. S.

*Improvements in Signalling Apparatus for Indicating the Presence of Explosive Gases in the Atmosphere.* E. Stern and M. Kaufmann, Cologne, Prussia. Eng. Pat. 13,668, August 30, 1889. 6d.

See under XI., page 81.

*An Improved Method of Charging Liquids with Gas.* H. H. Lake, London. From C. A. Catlin and C. L. Sweetland, Rhode Island, and R. Cox, New Jersey, U.S.A. Eng. Pat. 16,037, October 11, 1889. 8d.

The system and apparatus here described are intended to be applied to mixed gases only, the object being to separate a pure gas from the mixed gases, and simultaneously to combine the pure gas with the liquid under treatment in a simple and expeditious manner. This is done by allowing the gas to traverse the upper portions of a succession of closed vessels in a continuous stream, whilst the liquid occupies the lower part of the same vessels and is discharged intermittently from each vessel to the next in a direction contrary to the flow of the gas. The liquid in each vessel is agitated to meet and mingle with the gas in the form of spray, and may be retained there until any desired degree of saturation or chemical combination has been reached.

The drawing accompanying the specification shows one arrangement of apparatus, which has been designed with special reference to the production of an acid sulphate solution of magnesia, by exposing water holding powdered oxide of magnesium in suspension to the fumes of burning sulphur, which consists principally of sulphurous acid and nitrogen. It is, however, applicable also to the combination of other solutions and gases. The apparatus consists of several cylindrical closed vessels, which are placed one above the other with their axes horizontal. Through each passes a horizontal shaft driven by independent gearing, and provided with agitating blades, which are immersed in the liquid to about the height of the shaft. The upper portions of the vessels are connected externally by pipes at alternate ends, for conducting the gas which enters at one end of the lower vessel to ascend and successively traverse all the vessels from end to end. Other connexions exist, fitted, however, with shut-off valves, for discharging the liquid from one vessel to the other as may be required. The liquid first enters the upper vessel and the gas the lower, causing a contrary movement, with a view to allowing the enriched liquid, as it descends, to meet with gas of ever richer composition. The claim is for both the method and suitable apparatus.—B.

## II.—FUEL, GAS, AND LIGHT.

*The "Godillot" Furnace for Inferior Fuels.* Brüll. Bull. Soc. d'Encouragement, 1889, 289—296.

This is a report made to the *Société d'encouragement* by Mr. Brüll on behalf of the *Comité des arts mécaniques*, and refers to a fire grate and furnace arrangement perfected by G. Alexis-Godillot, of Paris, for burning inferior and indifferent fuels.

The object of the inventor is the construction of a furnace in which the refuse from many classes of manufacture can be satisfactorily utilised in the heating of boilers and for other mechanical purposes. Such refuse, which is generally produced in considerable quantities, consists of small particles of poor quality for heating purposes, and contains a great deal of moisture. It follows that a furnace for the proper consumption of this fuel must be capable of dealing with large quantities at a time, which makes it necessary to resort to automatic feeding. The ingenious way in which the inventor has carried out the requirements is shown in the accompanying drawings, in connexion with the heating of an ordinary French boiler.

The fire grate is composed of a number of horizontal steps one above the other, in the form of a half-circle in plan. It projects from an upright wall in front which carries the fuel inlet and the automatic feeding arrangement. The fuel being pushed continuously over the crown plate of the grate, descends all round over the steps, in a conical layer of material which gradually attains to incandescence, and arrives on the lower floor of the grate thoroughly consumed and burnt out. Referring to the drawings, A is the fire-

box; B the charging trough, in which works C, the feeding screw, which is provided with a tapering axle for the prevention of clogging; D is the half-circular step grate; E an opening for lighting the fire; F the ashpit; G a sight tube for

ascertaining the state of the fire and the accumulation of ashes on the ashpit floor; H the boiler with heaters underneath; I, I, channels for heating the air before it enters the fireplace; J, J, doors for access to the fireplace; K ashpit

Fig. 1.

Fig. 2.

Fig. 3.

door; L gearing for driving the feeding screw. This system of firing would appear to have now been in use for some time and been applied by the inventor to a variety of materials such as sugar cane megass, spent tan, wood shavings and bark cuttings, dye wood chips, refuse from flax fibres, &c., some of them containing more than 60 per cent. of water. Some 20 reports of varying applications of the furnace were submitted to the committee together with several records of special experiments. One of the latter is reproduced in the report and refers to experiments lasting for two days, carried out at Mulhouse-on-the-Rhine on the 3rd and 4th of June 1885 with two boilers having 2,150 square feet of aggregate heating surface, and fired with chips of wood. The table accompanying the report shows that the chips contained 62.3 per cent. of water and were burnt on the first day at the rate of 0.51 lb. of moist chips per square foot of heating surface per hour, during which time 0.73 lb. of water were evaporated per square foot of heating surface. On the second day the boilers were forced, and the consumption of fuel and water amounted to 1.22 and 1.8 lb. respectively, for the same units of time and surface. The amount of evaporation in each case was calculated from water at freezing temperature, and the steam taken at the average working pressure of 22 lb. per square inch above the atmosphere. The extent of the grate surface is not given in the report, and it is therefore impossible to calculate the amount of fuel that can be profitably consumed under the circumstances per square foot of grate surface, a point of equal importance with that of the consumption of fuel per square foot of heating surface.—B.

*Roumanian Petroleum.* S. Taubert-Bârladu. Zeits. f. angew. Chem. 1889, 605—606.

The richest petroleum districts of Roumania are situated at the south-east of the Carpathian Mountains, where the

oil is obtained at five different spots. In many places, especially at Ploiesti, the ground is charged with gas to such a degree that it is only necessary to bore a hole and a jet of inflammable gas issues at once. The working of the oil is conducted in shafts and galleries, the roofs and walls being closed in with boards. The total yield from Walachei amounts to 9,000 tons, and the product contains 20—23 per cent. of solid paraffin. It is exported to Vienna to a considerable extent and yields about 15 per cent. of petroleum naphtha on refining. The wells are 50—70 metres in depth, some as much as 120 metres. Deeper borings and large refineries have been established recently by foreign enterprise, and the output of oil has increased rapidly of late. The oil districts stretch along the southern side of the Carpathians to an extent at present unknown, in the provinces of Prahova, Dimbowitzza, and Buzen, and the fields appear to be connected with those of Galicia (this Journal, 1889, 768). Two varieties of crude oil are distinguished (1) *Păcura*; and (2) *Titeiu*. The latter contains the material for refining purposes and yields 78 per cent. of burning naphtha. It cannot be imported into Austria-Hungary on account of the high duty, but is freely exported to Germany (where there is no duty on the raw product), and after refining the lighting oil can be sold at 18.4 marks per hectolitre, whilst American oil commands 27 marks. (This refers to 1884.) The petroleum from Momesti and Cusin flashes at 17°—19° C. (10° below Russian petroleum), and begins to distil at 80°, yielding a large proportion of distillate up to 150°. Roumanian oils from eight districts are described by Istrati (Jahrbuch des Organischen Laboratoriums zu Bucharest, 1888—89) and contain from 42—65 per cent. of photogen, 5—20 per cent. of petroleum naphtha, and 11—25 per cent. of solid paraffin. The residues yield nearly 50 per cent. of photogen when carefully rectified. A sample from Păcureti (Prahova) yielded 50 per cent. of lighting oil of sp. gr. 0.800 and distilling between 125°

and 280°. Austrian and American crude petroleum both yield about 50–55 per cent. of good burning oil, whilst the Russian product does not give more than 20 per cent.  
—C. A. K.

*Relative Cost of Lighting by Gas, Petroleum, and Electricity.\** Gas World, 12, 65.

M. ROLLAND, engineer, Mons, recently read a paper before the Engineering Association of the Liège School, in which he discusses the relative cost of lighting by petroleum, coal gas, and arc and incandescent lamps. Full tables of his results are published in "Le Gaz," 1889–90, No. 4.

With regard to petroleum, his basis is a price of 6.54d. per gall., a consumption of 0.0248 gall. per hour, a light of 29.3 candles at 45° (40 candles horizontally), an allowance of 0.096d. per hour per lamp for attendance, and 0.14d. for upkeep, wicks, glasses, rags, &c.; then *per candle-hour* the petroleum costs (for light at 45°) 5.453 and the extras 4.704, or together, 10.157 thousandths of a penny. If the lamp consume 25 per cent. more petroleum for the same light, the hourly cost per candle power is 11.52 thousandths of a penny.

With regard to coal gas, he gives a series of data, from slit burners to Wenham No. 4:—

Types of Burners.	Angles.	Candle Power.	Hourly Consumption.	Cub. Ft. per Candle.
Slit burner.....	0	16.9	8.90	0.523
	45	17.2	9.04	0.526
Argand.....	0	21.9	8.44	0.385
	45	19.1	8.51	0.438
Clamond (new).....	45	21.1	6.71	0.318
Welsbach.....	0	14.4	3.36	0.233
	45	10.5	3.66	0.349
Cardinal.....	45	21.9	7.73	0.353
Siemens' regenerative, No. 3.....	0	65.3	16.25	0.249
	45	46.9	16.10	0.344
Wenham, No. 2.....	0	28.4	8.80	0.310
	45	41.5	9.07	0.204
	90	45.8	9.04	0.197
Wenham, No. 4.....	0	99.0	24.19	0.244
	25	152.0	24.16	0.159
	45	170.0	23.84	0.141
	65	200.0	24.19	0.121
	90	202.0	23.63	0.118

Selecting from these the data of illumination at 45° downwards as being the most generally useful, we have, taking the price of gas at 3s. 4½d. per thousand cubic feet—

Burners.	Cost of Gas per Candle Hour; Thousandths of a Penny.	Upkeep and Interest; Thousandths of a Penny.	Total Cost per Hour; Thousandths of a Penny.

„ No. 4..	5.731	0.970	6.701

\* Compare this Journal, 1888, 542.

Observe the quality of gas dealt with. With the first of these compare 28-candle gas in a 5-foot burner at a price of 3s. 6d., or 16-candle gas at 2s.; in this case the cost of gas is 7½ thousandths of a penny per candle per hour.

With regard to incandescent electric lamps, M. Rolland gives the candle-hour prices as follows: for an installation where there is spare power 15.36, for a special installation of a least 200 lamps with machinery 29.76, for a domestic installation 45.12 to 59.52 thousandths of a penny.

In the same address M. Rolland speaks of the efficiency of a gas burner varying according to the access of air and the temperature attained by the flame. According to him the luminous efficiency is almost exactly proportional to the temperature; whence, in part, the effect of heating the air supply. The heating of the incoming air should be done by the products of combustion, not by the flame directly. Heating the gas tends to produce deposits. The most advantageous supply of air is that at which the tip of the flame is just about to become brown; less than this, smokiness comes on; more than this, the flame becomes whiter but the lighting power falls off. To see this in an extreme form, double the length of the chimney of an argand lamp: the flame is whiter but the room is less brightly lit. This is of importance even when the air supply is heated. In larger burners the causes of loss of heat are less effective per unit of volume of the flame, and the incandescent shell is thicker in a more voluminous flame, whence the larger flame is hotter.

*Notes from the Caucasus.* Chem. Zeit. 13, 1159.

This is a reprint of an article on the inexhaustibility of the Balakhani naphtha basins, from the "Novoye Obozrenie." It goes over the same ground covered already by Professor Mendeléeff's article (this Journal, 1889, 753).—D. A. S.

*The Valuation of Coal-tar Pitch to be employed as a Binding Material for Patent Fuel (Briquettes).* F. Muck. Zeits. f. d. Berg.-Hütten und Salinenw. 37.

THE author gives the degrees of hardness, the temperature of softening, and the quantity and nature of the residue left on coking, for 24 samples of pitch. According to Preissig hard pitch is the more suitable for binding purposes, whilst Lunge is of opinion, and with reason, that soft pitch possessing a softening point of 50°–60° C. is the best. The author here remarks that in Westphalia soft pitches are generally employed. The tenacity of a sample is generally judged by the "chewing test," but in some instances this test is misleading and must be supplemented by a determination of the softening temperature. The commonly accepted opinion that soft pitches are blacker and more glossy than hard ones is pretty correct, but still mistakes may occur. The amounts of coke yielded by different samples of pitch vary very much and bear no relation to the degrees of hardness and temperatures of softening. Briquettes of good quality must not fall to pieces in the fire. According to the author this breaking up is due to the expansion of the pitch during heating. The author obtained from hard pitches in every case a voluminous residue on coking, whilst the soft pitches examined yielded, with one exception, a solid coke. It was found that those briquettes which easily crumbled in the fire were in all cases manufactured from pitch yielding a large residue on coking, whilst those which retained their shape when heated were prepared from soft pitch yielding a solid coke. For this reason the author earnestly recommends manufacturers to apply the coking test to those pitches which are to be used in the preparation of briquettes.—H. T. P.

See under XXIII., page 111.

*Aerated Fuel Company's System for Burning Oil.* Eng. and Min. J. 1889, 432.

In most systems for burning oil either a steam jet "atomises" the oil or the oil is heated in retorts and converted into gas before being burned. Such systems, from their nature, compel the use of more or less apparatus in the fire-box or furnace—in some cases the retort being placed therein, while in others the fire-box is filled with fire-brick, or other refractory material, to be heated and then used as a means to ignite the fuel. In this method compressed air is used for atomising the oil, and the pressure is so well governed that, no matter what the boiler pressure may be, a uniform pressure of five or ten pounds is kept, or whatever number of pounds per square inch is best suited for the perfect combustion of the oil, regardless of what may be on the boiler. This method of governing must result in a perfectly uniform heat of almost any intensity desired.

Another point of great advantage is that, where possible, the burners are placed so that the orifices are exactly opposite each other, thus intensifying the heat and burning the oil so completely that there is no dripping and consequently no necessity for a drip-pan or fire-brick to catch the oil that escapes from the burners without being atomised.

By this arrangement of burners, "brick arches," "breakers," or other devices in the fire-box of the boilers are not needed, so that in the event of the oil supply giving out from any cause, a wood or coal fire can be immediately built without any delay whatever, or, if occasion should ever require, both coal and oil can be burned at the same time.

It is claimed that one pound of oil will do the work of from three to six pounds of the best hard coal in forges, and do it better. There is less liability of overheating or burning stock, and in fact it is every way superior to and cheaper than coal, and only equalled by natural gas in economy and cleanliness. The system can be adapted to any forge, but as it is necessary to use from 10 to 25 pounds air pressure per square inch, a compressor of some kind is necessary. All oil can be below the burners, thus preventing the flooding of furnaces through carelessness, and meeting the requirements of the insurance companies.

Fig. 1 shows the application of this system at the Upson Nut Company's plant, at Cleveland, O., for the forging of nuts and bolts. The result here seems to prove most satisfactory, the cost of the oil being much less than coal, while the dies wear longer as there is less scale on the work, and in addition the uniformity of heat enables the workmen to do more and better work.

Fig. 1.

Fig. 2 shows a forge adapted to a large variety of general work. One cylinder containing six burners is placed on one side only, leaving one end open to receive the work. Both ends may be left open, if desired, for heating long pieces of iron or steel in the centre. By putting in an adjustable or moveable brick partition the operator may shut out as many burners as are not wanted, reduce the area of the fire-box, and only use one or two burners as may be best suited to the work being done. For general work this is a standard forge, and is used by the Boston and Albany railroad for hardening and tempering locomotive springs, heating large pieces of steel for forging, and for any work that requires a high degree of heat at short notice.

Fig. 2.

The most important feature about the system seems to consist in the placing of the oil supply at a level lower than the fire, thus entirely obviating the risk of sudden combustion of a large amount of oil, with its consequent danger, either through carelessness or unavoidable accident.

—O. H.

#### PATENTS.

*Improvements in or appertaining to the Separating and Collecting of the Solid Materials from Fume, Smoke, or the like.* W. P. Thompson, Liverpool. From F. P. Dewey, Washington, U.S.A. Eng. Pat. 14,644, September 17, 1889. 6d.

SCRUBBING with water often fails to remove the solid particles from fume or smoke, owing to the fact that they pass through the apparatus without being wetted thereby. It is proposed, therefore, to use instead various organic chemicals, either in aqueous solution or without water at all. The organic substances suggested are "crude petroleum and the products of its refining (except coke), organic acids and salts of the same, alcohols and alcoholic derivatives, waxes, fats, resins, turpene, bisulphide of carbon, and fixed drying and essential oils."—A. R. D.

*Apparatus for Manufacturing Heating Gas.* A. Kitson, Philadelphia, U.S.A. Eng. Pat. 14,922, September 21, 1889. 8d.

A GAS generator is divided by a vertical partition into two fuel chambers connected at the bottom by a base chamber. A mixture of highly-heated air and steam is blown in at the top of one chamber downwards through the incandescent fuel therein, and, passing through the base chamber, ascends through the second fuel chamber, whence it issues at the top as a heating gas of high quality, free from carbonic acid.

After working in this way for a certain time, the direction of the current is reversed, the blast being admitted at the top of the second fuel chamber, and so on alternately. In the base chamber, and about the bases of the fuel chambers, are disposed coils wherein the necessary heating and super-heating are performed. If desired the blast may be driven downwards simultaneously through both generators, the gases mingling in the base chamber, and being drawn thence for consumption. This arrangement allows the introduction of a hydrocarbon along with the air-and-steam blast, into one fuel chamber at a time if so preferred.—A. R. D.

*Desulphurising the Lime used in Gas Purifiers and recovering the Sulphur therefrom.* W. T. Walker, London. Eng. Pat. 15,655, October 30, 1888. 4d.

CARBONIC acid gas (preferably that "which is driven off in revivifying the lime from carbonic acid gas") is introduced into the lime which has become charged with sulphur or sulphur compounds, the carbonic acid displacing the sulphur compounds which pass into any suitable appliance for receiving or recovering the sulphur, for example, into a gas-holder, or direct into a condenser and scrubber, and thence into a "Claus Patent Kila," in which the sulphur is obtained and deposited.—F. S.

*Improved Process of and Apparatus for Manufacturing Heating or Fuel Gas.* B. Loomis, Hartford, U.S.A. Eng. Pat. 15,983, November 5, 1888. 8d.

THIS improved process relates to the alternate production of producer-gas and water-gas. In making the former, air with a little steam is drawn downwards through the fuel by an exhaustor. By this means the tarry and other vapours distilling from the newly-charged layers of coal are brought into contact with the heated fuel and converted into fixed gas. This arrangement also obviates many inconveniences that have arisen when the attempt has been made to attain the same end with a blast forced downwards by pressure applied above. The producer-gas, being drawn off at the bottom, is caused to pass first through a flue system (which acts subsequently as a steam superheater for the production of water-gas), and then through a water cooler before reaching the exhaustor. When the fuel in the generator is raised to incandescence the exhaustor is stopped, and steam superheated by traversing the flue system above mentioned, is admitted at the bottom of the generator. The resulting water-gas is drawn off at a point between the incandescent fuel and the recently added coal distilling above it, so that the vapours arising from the latter mix with the water-gas, and are fixed without undergoing a destructive decomposition.

—A. R. D.

*Improvements in the Manufacture of Coke and in the Ovens and Apparatus employed therefor.* J. Nimmo, Edinburgh, and J. Scotland, Airdrie. Eng. Pat. 18,918, December 27, 1888. 8d.

THE floor of the coke oven is moveable and mounted upon a horizontal axis, so that it can be made to tilt and discharge the coke upon a sloping screen placed below. The dust and refuse, passing through this screen, fall into a suitable receptacle, while the coke proper rolls forward into a bucket where it is quenched before being discharged into waggons for removal.—A. R. D.

*Improvements in or relating to Furnaces for Utilising Hydrocarbon as Fuel, and in Burners and operating Devices applicable therefor.* G. C. Dymond, London. From the Aërated Fuel Company, Springfield, U. S. A. Eng. Pat. 18,954, December 28, 1888, 11d.

A CLOSED tank is kept filled to a certain level with liquid hydrocarbon by a float valve of simple construction. Attached to this tank is a burner, formed injectorwise, so that compressed air forced into the tank leaves the burner nozzle mixed with the hydrocarbon in an atomised form. This

blast entering the furnace is caused to play upon some solid portion thereof, which soon becomes highly heated and completes the atomisation of the fuel, so that perfect combustion is secured and a very intense heat obtained (see previous page).—A. R. D.

*Improvements in Coke Ovens.* H. Simon, Manchester. Eng. Pat. 1271, January 23, 1889. 8d.

THESE improvements are intended to facilitate the removal of coke from those ovens which, being made in the form of vertical shafts somewhat wider at the bottom than at the top, allow their contents to drop out when a door at the bottom is opened. Extending lengthwise below the group of ovens is formed a firebrick structure sloping downwards each way from the central line, the slopes terminating in gratings. When discharged from the ovens above, the coke tumbles down the slope and over the grating (whereby the small is removed) into waggons placed below to receive it. The firebrick structure is utilised as a regenerator wherein the waste furnace gases are caused to heat the air required for combustion.

—A. R. D.

#### IV.—COLOURING MATTERS AND DYES.

*On Dehydrothioltoluidine.* P. Jacobsen. Ber. 22, 330—335.

THIS is one of several researches which have recently been carried out for the purpose of determining the constitution of primuline. The author heated this colouring matter with phosphorus and hydriodic acid to 200° for 8—12 hours. On opening the tubes H<sub>2</sub>S was evolved. The contents were mixed with water, filtered, and the residue extracted with hydrochloric acid. From this solution the base was precipitated with ammonia and crystallised several times from alcohol. The formula of the body is C<sub>11</sub>H<sub>12</sub>N<sub>2</sub>S, and it is identical with a thio-compound prepared by heating paratoluidine with sulphur in the proportions of 10:6 to 190°, and finally to 220°. Almost all toluidine had disappeared after six hours. To separate the dehydrothioltoluidine from other compounds, the melt is extracted with hot hydrochloric acid (sp. gr. 1.06), and the solution precipitated with water; the precipitate is purified by repeating this treatment, and finally separated by diluting and neutralising with ammonia. After crystallising several times from alcohol the melting point rises to 190°—191°, which is identical with that of the dehydrothioltoluidine obtained by the previous method. All its solutions exhibit a very fine blue fluorescence. In warm concentrated HCl the white base dissolves readily with an orange colour. On adding water a light yellow precipitate of the base is produced, changing to white on adding ammonia. As a further proof of the identity of the thio body obtained from sulphur and toluidine, and of that prepared from primuline by reduction, the author converted each into the phenol by the action of nitrite, and the phenol again into an acetyl derivative. Complete similarity of the products confirmed the above assumption of identity.

—A. R.

*The Action of Sulphur on certain Primary Aromatic Amines.* R. Anschütz and G. Schultz. Ber. 22, 580—586.

THE authors confirm the statements of Jacobsen (see previous abstract) concerning the production of dehydrothioltoluidine from sulphur and paratoluidine, and also describe the action of sulphur on amido-*m*-xylene. On heating these bodies in the proportion of two mols. of xylidine to two mols. of sulphur to 200°, a base of the composition C<sub>10</sub>H<sub>10</sub>N<sub>2</sub>S, readily soluble in alcohol, is the principal product. Its sulpho-derivatives are colourless.

If, however, more sulphur be taken than corresponds to the above proportions, and the temperature be raised to

200°—250° for some time, the chief product is insoluble in alcohol, and on sulphonating it the sodium salt is found to possess the property of dyeing un mordanted cotton yellow.

For purifying the first mentioned thio base of the formula  $C_{16}H_{16}N_2S$ , it is dissolved in a mixture of equal parts of sulphuric acid and water. On gradually adding water a yellow crystalline sulphate is precipitated. This is washed to remove xylydine sulphate, and then converted into the base with caustic soda. The crude product is now distilled, the distillate dissolved in a hot mixture of equal parts of sulphuric acid and water, and a sufficient quantity of water is added to cause a distinct turbidity. On cooling nearly all the sulphate crystallises out. After recrystallising it from alcohol it is converted into the base, which in its turn is crystallised from boiling alcohol, whence it is obtained in yellowish-white prismatic crystals. The base melts at 107°, and boils under a pressure of 13 mm. at 282°—284°. It contains only one amido group which can be diazotised. The azo-dyes prepared from it have the characteristic property of dyeing un mordanted cotton in a Glauber-salt bath. The acetyl derivative of the thio base is described, melting at 107°. On adding bromine dissolved in chloroform to the base a crystalline body of the formula  $C_{16}H_{16}N_2SBr_2 + CHCl_3$  separates.

Though the sodium salt of the sulpho-derivative of the base does not dye cotton, it combines with it and imparts a vivid blue fluorescence. Like primuline it can be diazotised on the fibre and further combined with naphthol and its sulphonic acids, forming dyes. Sulphur acts on amido-*p*-xylene at a temperature below 200° with formation of a thio base, readily soluble in alcohol, melting at 144°. Azo-dyes prepared from this body do not dye cotton.

When 3—4 parts of  $\psi$ -cumidine are heated with 1 part of sulphur to 185°—195°, until the evolution of  $H_2S$  ceases, the product is found to consist of two bases which are separated by treating with alcohol; the lemon-yellow portion which remains undissolved is with difficulty soluble in boiling alcohol. Its formula is  $C_{15}H_{20}N_2S$ , and its melting point 183°. From the alcoholic extract another base is obtained, melting at 123°, which has not yet been analysed.—A. R.

#### *Decomposition of Aromatic Diazo-Compounds in Alkaline Solution.* P. Friedländer. Ber. 22, 587.

OF the two methods hitherto at our disposal for eliminating aromatic amido groups, Griess' method of boiling the diazo-compound with alcohol labours under the disadvantage that phenolic others are produced along with the desired hydrocarbon, sometimes, in fact, to the exclusion of the latter, while E. Fischer's method of oxidising the hydrazine with ferric chloride, though giving generally better yields, is somewhat complicated. The author describes a new method, which is particularly applicable if the resulting products are insoluble in alkali. It is based on the fact that most diazo bodies dissolve in an excess of alkali in the cold without decomposition. On adding an alkaline reducing agent, preferably an alkaline solution of stannous chloride, and cooling with ice, nitrogen is at once evolved, and hydrogen takes its place. Thus aniline yields benzene and sulphamic acid benzene sulphonic acid.—A. R.

#### *On Acid Green.* P. Friedländer. Ber. 22, 588.

THIS product, which is now extensively used for dyeing wool in an acid bath, is prepared from ethylbenzylamine. The latter is readily obtained by heating benzylaniline and ethyl iodide or ethylaniline and benzylchloride. The new base boils at 285° with slight decomposition. The salts are very soluble. It behaves just like dimethylaniline towards benzylaldehyde; in presence of  $ZnCl_2$ , conc.  $H_2SO_4$ , or anhydrous oxalic acid, condensation is effected by heating a few hours to 100°—110°. After boiling out with water, the residue may be crystallised from acetone. The condensation product melts at 115°—116°. Its composition is that of a diethyldibenzylamidotriphenylmethane, as proved by its behaviour towards oxidising agents. Chloranil converts it into a dye of the malachite-green type. On heating the

lence base with fuming sulphuric acid at 100°, di- and tri-sulphonic acids are produced, which separate from their aqueous solutions as resinous masses on addition of sodium sulphate. On treating with the requisite quantity of lead peroxide in the usual manner, the very soluble green dyes are obtained. In evaporating the sodium salt a certain loss cannot be avoided, probably owing to the partial oxidation of the benzyl groups to benzaldehyde or its sulphonic acid.

*p*-Nitrobenzaldehyde, when condensed with ethylbenzylaniline yields a lence base, which, by reduction, sulphonating, and oxidation, is converted into a very blue "acid violet" (the sulphonic acids of *p*-amidodiethyldibenzylidiamidotriphenyl carbinol).—A. R.

#### *On the Reduction of Amidoazonaphthalene.* P. Friedländer. Ber. 22, 589.

ACCORDING to W. H. Perkin and Church, pyridine is a by-product of the reduction of amidoazonaphthalene. The author is unable to confirm this statement. Having reduced 100 grms.  $\alpha$ -amidoazonaphthalene with an acid stannous chloride solution, and concentrated the solution, the  $SnCl_2$  double compound of naphthylenediamine and of naphthylamine separated out. Any pyridine present should be found in the mother-liquor. After removing tin with zinc, the solution was treated with potassium chromate, which converts the naphthalene bases into insoluble dyes, but which would leave any pyridine present intact. After distilling with steam the distillate gave no reaction with bromine water, this being the most delicate reaction for pyridine, detecting so little as 1 part in 30,000.

Amidoazonaphthalene is best prepared by treating 1 mol.  $\alpha$ -diazonaphthalene with 1 mol.  $HCl$  naphthylamine in a cold aqueous solution, neutralising with soda and crystallising from xylene.—A. R.

#### *On Naphthoquinonedichloro-imide.* P. Friedländer and O. Böckmann. Ber. 22, 590.

NAPHTHYLENEDIAMINE ( $\alpha^1 \alpha^4$ ) dissolved in an excess of hydrochloric acid, was treated with a solution of chloride of lime so long as a precipitate was formed. This was collected, washed, and crystallised from alcohol and xylene. The light yellow needles obtained melt at 136°—137°, and possess an intense smell of quinone. The body has both the composition and properties of a quinoneimide. Concentrated  $HCl$  acts on it in the cold even, but instead of a tetrachlorodiamine being formed, chlorine is evolved, and dichloro- $\alpha$ -naphthoquinone results. In paradiamido derivatives of naphthalene, the connexion of the nitrogen atoms seems to be much looser than in the benzene nucleus. On heating naphthoquinonediimide with sodium bisulphite, it dissolves with formation of a sulphonic acid of naphthylenediamine or amidonaphthol. The amide also reacts with primary and tertiary amines of the naphthalene and benzene series with formation of coloured condensation products.

—A. R.

#### *The Reactions of Phenylhydrazine and Hydroxylamine.* E. Fischer. Ber. 22, 1930—1936.

PHENYLHYDRAZINE and hydroxylamine act similarly towards aldehydes, ketones, nitrous acid, and diazo compounds.

The author finds further that both combine with hydrocyanic acid under special conditions, and he has succeeded also in preparing a compound of cyanogen and hydroxylamine analogues to that of cyanogen and phenylhydrazine, which is already known. If cyanogen is passed into an aqueous solution of hydroxylamine, cooled to 0° until a white precipitate begins to form, and the solution evaporated, a crystalline mass remains. The compound has the composition  $C_2H_6N_4O_2$ , and is formed according to the equation—

The compound belongs to the class of amidoxins, and may be called oxalamidoxim,

It is decomposed on boiling with dilute hydrochloric acid. It combines with acetic anhydride to form a new compound.

The white precipitate formed with an excess of cyanogen is not a homogeneous substance, and is probably mainly composed of a compound of oxalamidoxim and cyanogen. Phenylhydrazine combines with hydrocyanic acid to form a compound of the formula  $\text{C}_7\text{H}_9\text{N}_3$ . This is probably an amidine of the formula—

to which the author gives the name methenylphenylazidine.

Whereas hydroxylamine combines readily with cyanic acid to form a urea derivative, phenyl cyanate does not act so readily, and the compound formed consists of 2 molecules of the cyanate to one of hydroxylamine, and has the formula  $\text{C}_{14}\text{H}_{13}\text{N}_3\text{O}_3$ .

The simple urea derivative  $\text{C}_6\text{H}_5\text{NH} \cdot \text{CO} \cdot \text{NH}_2\text{O}$  may be obtained by adding phenyl cyanate slowly to a large excess of hydroxylamine.

Phenyl mustard oil and hydroxylamine combine with elimination of all sulphur according to Schiff; but if the action is carried on in the cold, colourless crystals of phenyloxysulphourea,  $\text{C}_6\text{H}_5 \cdot \text{NH} \cdot \text{CS} \cdot \text{NH}_2\text{O}$  are formed.

Carbonylsulphide in ethereal solution combines with phenylhydrazine to form the crystalline compound—

Heated to  $100^\circ$  in a closed tube it forms diphenylcarbazine,  $(\text{C}_6\text{H}_5\text{N}_2\text{H}_3)_2\text{CO}$ , with chloroformic ether, phenylhydrazine forms a compound  $\text{C}_6\text{H}_5\text{NH} \cdot \text{NH} \cdot \text{COOC}_2\text{H}_5$ . Carbonyl chloride also reacts with phenylhydrazine.—J. B. C.

#### The Sulphonic Acids of Benzidine and Benzidine Sulphone.

P. Griess and C. Duisberg. Ber. 22, 2459—2474.

BENZIDINE monosulphonic acid was obtained by one of the authors in the year 1881 by heating benzidine in an oil-bath at  $170^\circ$  with double its weight of fuming sulphuric acid. A small quantity of monosulphonic acid was so obtained which was erroneously taken to be a disulphonic acid isomeric with the well-known disulphonic acid which forms the chief product. The best method of making the monosulphonic acid consists in heating the acid sulphate of benzidine either in an oven for a short time at  $220^\circ$  or spread on enamelled iron trays in an air-bath for 24 hours at  $170^\circ$ , the mass containing in the latter case a slight excess of sulphuric acid. The impure product is extracted with alkali and the monosulphonic acid precipitated therefrom by the addition of acetic acid. It is purified by repetition of this treatment and is finally obtained chiefly in the form of four-sided plates by adding acetic acid to a boiling ammoniacal solution. It crystallises from hydrochloric acid in small tables, forms a sparingly soluble barium salt crystallising with five molecules of water, but is chiefly distinguished from the disulphonic acid by its yielding an easily soluble tetrazo derivative. This tetrazo derivative combines with phenols (naphthols) and amines (naphthylamines) or carboxylic or sulphonic acids of the same, forming dyestuffs of shades in general intermediate between those obtained from tetrazodiphenyl and tetrazodiphenyldisulphonic acid, and capable of dyeing unmordanted cotton in an alkaline bath.

Benzidine monosulphonic acid hydrochloride is made by dissolving the free sulphonic acid in hot hydrochloric acid diluted with about three parts of water. It separates out in the anhydrous state on cooling. The hydrochloric acid can be removed by treatment with boiling water.

Benzidine metadisulphonic acid is easily produced by heating benzidine with excess of ordinary concentrated sulphuric acid or by heating acid benzidine sulphate, with or without addition of sulphuric acid, to a higher temperature and for a longer time than suffice for the formation of the monosulphonic acid, as in the following example:—One part of benzidine sulphate is mixed with about two parts of sulphuric acid, the mixture heated at  $210^\circ$  for 36—48 hours and the disulphonic acid then separated from the small quantity of monosulphonic acid simultaneously formed. The yield amounts to about 90 per cent. As the properties of this acid have been previously described, it only remains to mention that the dyes it yields have less affinity for the cotton fibre than those obtained from the monosulphonic acid, but are generally of bluer shade than those made from the latter.

Benzidine orthosulphonic acid, formed by the reduction in alkaline solution and subsequent molecular transformation of *m*-nitrobenzene sulphonic acid, yields dyes for the most part incapable of dyeing unmordanted cotton.

The difference in behaviour of benzidine and azo compounds of the same towards sulphuric acid is striking. For whilst, for example, benzidine is attacked by fuming sulphuric acid only at a temperature of  $100$ — $120^\circ$ , the insoluble azo body produced by the combination of tetrazodiphenyl and 2 molecules of  $\beta$ -naphthylamine is sulphated by fuming acid in the cold, the sulphonic acid groups entering the benzidine nucleus and forming products identical with those produced from  $\beta$ -naphthylamine and benzidine mono- or disulphonic acid.

Benzidine trisulphonic acid is formed along with the tetrasulphonic acid by heating benzidine sulphate with a large excess of concentrated sulphuric acid to  $180^\circ$ — $190^\circ$  or by adding fuming sulphuric acid to a solution of benzidine in sulphuric acid heated to  $160^\circ$ — $170^\circ$ , and then heating till a sample, on testing, shows the presence of very little disulphonic acid. The barium salt of the trisulphonic acid crystallises in the form of white indistinct prisms containing 12 molecules of water, and is freely soluble in warm water, that of the tetrasulphonic acid being difficultly soluble. Advantage is taken of this fact in the separation of the two acids. The free trisulphonic acid crystallises with 2 molecules of water in delicate white plates.

Benzidine tetrasulphonic acid is formed together with the trisulphonic acid as mentioned above. It crystallises with 6 molecules of water in small white glistening needles; the barium salt forms white needles containing 8 molecules of water of crystallisation.

Benzidine sulphone is obtained on heating benzidine sulphate with excess of fuming sulphuric acid at a temperature below  $120^\circ$ . In order to purify the crude product it is extracted with boiling alcohol, dissolved in hydrochloric acid, and precipitated with sodium hydrate, by which treatment it is obtained as an anhydrous, bright yellow, finely crystallised mass, insoluble in water, alcohol, ether, and benzene. It melts at  $350^\circ$ . It possesses very weak basic properties, but its salts are decomposed when treated with a large amount of water. Strong solutions of potassium hydrate and hydrochloric acid, even at high temperatures, are without action on it. Fused with sodium hydrate at  $180^\circ$  it yields mono-hydroxy-benzidine. When the amido groups are removed by means of the diazo reaction, diphenylene sulphone identical with that prepared by Stenhouse and Graebe is obtained. The sulphate of benzidine sulphone crystallises with  $\frac{1}{2}$  molecules of water.

The azo dyes formed from benzidine sulphone are characterised by their decided blue shade. As is well known, tetrazodiphenyl combines with naphthionic acid, forming "Congo red." Now, tetrazodiphenyl sulphone gives with this acid a full violet. Again, tetrazodiphenyl yields with naphthol sulphonic acid ( $\text{OH}:\text{SO}_3\text{H} = 1:4$ ) a Bordeaux red dyestuff, "azo-orceiline," whilst tetrazodiphenyl sulphone under the same conditions forms a dull blue.

Benzidine sulphone monosulphonic acid is made by heating benzidine sulphone with fuming sulphuric acid to  $100^\circ$ . According to the duration and temperature of the operation, different sulphonic acids, namely, mono-, di-, tri-, and tetrasulphonic acids are obtained, of which the two former are sparingly, the latter freely, soluble in water. The

monosulphonic acid crystallises with 2 molecules of water, the barium salt with  $3\frac{1}{2}$  molecules.

Benzidine sulphone disulphonic acid forms pale yellow needles or prisms containing  $1\frac{1}{2}$  molecules of water of crystallisation. It is difficult to prepare, as the sulphonation tends to proceed further to the formation of the tri- and tetrasulphonic acids. The barium salt contains  $4\frac{1}{2}$  molecules of water of crystallisation. The sodium salt is easily soluble in hot, sparingly soluble in cold water, and crystallises in large yellow needles. The tetrazo derivative of this acid separates out from solution as a pale yellow voluminous precipitate which on standing becomes powdery and apparently anhydrous. Combined with naphthols or naphthol sulphonic acids, bluish red to violet dyes are formed; with the naphthylamines and naphthylamine sulphonic acids red to bluish violet dyes are obtained. But the most important dyestuffs are those formed on combination with the alkylated and phenylated naphthylamines, which not only possess the valuable property of dyeing un mordanted cotton, but, with the assistance of sodium sulphate, can be used to dye wool shades of blue fast to milling. These dyestuffs are known as "sulphone-azurines."

Ortho-toluidine is acted upon similarly to benzidine by concentrated, monohydrated, and fuming sulphuric acid, the two former producing mono- and disulphonic acids, whilst fuming acid forms toluidine sulphone and mono- and disulphonic acids of the same. The methods of preparing these substances are similar to those employed for making the corresponding benzidine compounds. Toluidine acid sulphate heated in an oven yields a mixture of mono- and disulphonic acids, separable by acetic acid. The monosulphonic acid is difficultly soluble in water; its barium salt crystallises with 4 molecules of water. Like that of benzidine monosulphonic acid, the tetrazo derivative is easily soluble. On the other hand, the disulphonic acid of toluidine, unlike that of benzidine, is easily soluble. The sodium salt crystallises with either 3 or 4 molecules of water, the barium salt in needles with 3 molecules. Toluidine sulphone closely resembles the benzidine compound, but does not yield sulphonic acids so easily as the latter.—E. B.

*The Chlorination and Bromination of Aniline, Ortho-toluidine, and Paratoluidine in presence of Excess of Mineral Acid.* R. Hafner. Ber. 22, 2524—2541.

ANILINE dissolved in 97 per cent. sulphuric acid is only slightly attacked by chlorine even after long exposure to the action of the gas, a small amount of *p*-chloraniline being so produced. Ortho- and *p*-toluidine, under similar conditions, are more freely attacked, the former yielding a monochlorinated derivative of unknown constitution, the latter a little *m*-chloro-*p*-toluidine ( $\text{CH}_3 : \text{Cl} : \text{NH}_2 = 1 : 3 : 4$ ), but chiefly *o*-chloro-*p*-toluidine ( $\text{CH}_3 : \text{Cl} : \text{NH}_2 = 1 : 2 : 4$ ).

With 65 per cent. sulphuric acid the chlorination is incomplete, but it is complete when 40 per cent. acid is used, symmetrical trichloraniline being chiefly formed with small quantities of lower chlorinated anilines and phenols, and, in the case of the weaker acid, also tarry matters.

Similar to the effect of concentrated sulphuric acid is that of 40 per cent. hydrochloric acid, *p*-chloraniline and apparently isomeric monochloro- and dichloroanilines being formed, but a portion of the aniline remaining intact. All the aniline is acted upon when dissolved in 30 per cent. hydrochloric acid, the products being *p*-chloraniline, dichloroaniline and trichloraniline, the last-named being also formed together with phenols and tarry matter from a solution in 20 per cent. acid.

In 40 per cent. hydrochloric acid *p*-toluidine is transformed into *m*-chloro-*p*-toluidine, *o*-chloro-*p*-toluidine, *m*-dichloro-*p*-toluidine ( $\text{C}_6\text{H}_3 : \text{NH}_2 : \text{Cl} : \text{Cl} = 1 : 4 : 3 : 5$ ), and chlorinated cresols.

Treatment of aniline dissolved in 97 per cent. sulphuric acid with bromine for 10 days, with frequent stirring, was practically without effect. At the end of three months a small amount of tribromaniline was formed. Bromine was likewise without action upon *o*-toluidine in 97 per cent. acid.

On addition of iodine, bromine acts, to some extent, on aniline dissolved in 97 per cent. sulphuric acid, forming chiefly symmetrical tribromaniline.

In 40 or 65 per cent. sulphuric acid aniline is acted upon by bromine with the formation of tribromaniline, brominated phenols being also produced in the case of the weaker acid. Concentrated hydrochloric acid does not protect aniline or *o*-toluidine from the action of bromine, which forms respectively tribromaniline and *m*-dibromo-*o*-toluidine ( $\text{CH}_3 : \text{NH}_2 : \text{Br} : \text{Br} = 1 : 2 : 3 : 5$ ), with scarcely any by-products. Symmetrical tribromaniline is at once formed as a white precipitate on adding excess of bromine to a solution of aniline hydrobromide in potassium bromide. It is noteworthy that the compound, *o*-chloro-*p*-toluidine ( $\text{CH}_3 : \text{Cl} : \text{NH}_2 = 1 : 2 : 4$ ), is, as far as known, formed only as described above.—E. B.

*The Colouring Matters of the Triphenylmethane Group.*  
E. Noetting. Ber. 22, 2573—2582.

I. *The Formation of Rosaniline.*—The action of oxidising agents, or more particularly of arsenic acid, upon those homologues of aniline in which both the ortho and meta positions relatively to the amido group are occupied, has been further investigated (see this Journal, 1888, 744). The following five compounds:—

Two orthoxylinides—

two cumidines—

and duridine—

were submitted to oxidation with arsenic acid, alone and in conjunction with *p*-toluidine, asymmetric-*m*-xylylidine, and mesidine (cumidine). Magenta was not in any case obtained, but, instead, yellow or violet-grey dyestuffs, presumably of the acridine class. It therefore appears that the presence of a methyl group in the meta position to the amido group in an amine which has its para position free, renders it incapable of forming magenta when oxidised with a paramethylated amine. The author, further, decides the question as to the behaviour on oxidation of the meta-methylated derivatives of the paramethylated amines of the first group in Rosenstiehl and Gerber's classification. Experiments were made with the following bases:—

Paraxylylidine—

three cumidines—

and duridine—

All of these, when oxidised in conjunction with aniline, orthoxylylidine, or adjacent metaxylylidine, yield magenta in large quantity. It thus seems that a paramethylated amine is always suitable for making magenta, whether its meta position is substituted by a methyl group or not. Each of the ten paramethylated homologues of aniline, when oxidised together with two molecules of aniline, ortho-toluidine, or adjacent metaxylylidine, forms a magenta. Thus a series of 30 magentas is obtained. By taking equal molecules of two amines, that is, for instance, single molecules of aniline and ortho-toluidine, instead of two molecules of one of them, the number of magentas is increased to 60. But some of these are alike, so that the total number becomes reduced to 52. The following magentas are identical, namely, those obtained from:—

1. Metaxylylidine and 2 mols. of aniline = *p*-toluidine, *o*-toluidine, and aniline.
2. Mesidine and 2 mols. of aniline = *p*-toluidine, adjacent *m*-xylylidine, and aniline.
3. Metaxylylidine, *o*-toluidine, and aniline = *p*-toluidine and 2 mols. of *o*-toluidine.
- 4 and 5. Mesidine, *o*-toluidine, and aniline = *m*-xylylidine, adjacent metaxylylidine, and aniline = *p*-toluidine, adjacent *m*-xylylidine, and *o*-toluidine.
6. Mesidine, adjacent *m*-xylylidine, and aniline = *p*-toluidine and 2 mols. of adjacent *m*-xylylidine.

7. Mesidine and 2 mols. of *o*-toluidine = *m*-xylydine, adjacent *m*-xylydine, and *o*-toluidine.

8. Mesidine, adjacent *m*-xylydine, and *o*-toluidine = *m*-xylydine and 2 mols. of adjacent *m*-xylydine.

II. *Combinations of Tetramethyldiamido-benzhydrol and -benzophenone.*—Since it appeared that magentas containing one metamethylated benzene nucleus can exist, it seemed probable that tetramethyldiamido-benzhydrol would condense with metamethylated amines whose para positions were free. Such was found to be the case, the leuco-bases of violet-blue colouring-matters being so produced. In the same way it was found that condensations could be effected with such metamethylated bases as monomethyl-*m*-toluidine, dimethyl-*m*-toluidine, diethyl-*m*-toluidine, diethyl-*p*-xylydine, and adjacent diethyl-*o*-xylydine. The tertiary bases just mentioned also condense with the ketone-base in presence of phosphorus oxychloride with the direct formation of blue violet colouring-matters. Finally, meta-chloro-, bromo-, and iodo-anilines condense with the hydrol-base forming the leuco-bases of violet dyes of slightly less bluish tone than those of the *m*-toluidine derivatives.

III. *Quinolyldiphenylmethane Colouring Matters.*—It has been shown by E. and O. Fischer that the substitution by an acetyl group of one of the hydrogen atoms in the amido group of tetramethyltriamidotriphenylmethane renders the shade of the resultant body green, whereas substitution by methyl increases the blueness of the violet dye. It seemed of interest to ascertain the effect of submitting tetramethyltriamidotriphenylmethane to Skraup's reaction to obtain, if possible, a body of the following constitution:—

This body was easily obtained. On oxidation it yielded a blue-green dyestuff, exceedingly fugitive to light, and consequently without technical value. It thus appears that the quinolination of the phenyl-amido group has the same effect as the acetylation of the same. It remains to be seen whether this quinoline green is identical with that obtained by condensing quinoline with tetramethyldiamidobenzophenone. The isomeric tetramethyltriamidotriphenylmethane produced by the reduction of metanitrobenzaldehyde-green yields a quinoline derivative which also on oxidation forms a green dyestuff.—E. B.

*Report No. I. On New Colouring Matters.* E. Knecht. Jour. Soc. Dyers and Colourists, 1889, 106—107.

THESE colours may be conveniently classified as (1) dyes used principally for wool and silk, and (2) dyes used principally for cotton, and again into substantive and adjective dyes.

#### 1. DYES USED PRINCIPALLY FOR WOOL AND SILK.

(a.) *Substantive Dyes.*—*Jet Black.*—This dye appears in commerce as a dark brown powder in two shades, G. and R., soluble in water with a dark violet colour. The aqueous solution of *Jet black G.* is turned green on the addition of dilute sulphuric acid, while ammonia turns the original violet solution redder. Stannous chloride produces a dark-coloured precipitate. *Jet black R.* yields with sulphuric acid a blue-black precipitate; ammonia produces no change, and stannous chloride a black precipitate. Both shades appear to be mixtures of dyes which resemble in their general reactions the direct cotton dyes.

The application of *Jet black* in wool dyeing is somewhat remarkable, inasmuch as it is best applied (when used as a self-colour) in a neutral bath containing about 20 per cent. of common salt. The dye-water is not exhausted. *Jet black* yields thus fine shades of black on wool, which are not

materially altered by exposure to light for one month, nor by treating for 15 minutes in a 1 per cent. soap solution at 60° C.

*Jet black* also dyes wool in an acid bath, and may, therefore, be used along with acid dyes for compound shades. When dyed on the fibre, shade G. is turned green when boiled with dilute sulphuric acid (1 : 10). Ammonia partially restores the colour. Stannous chloride turns the fibre reddish brown, and strong sulphuric acid extracts the dye with a blue colour. Nitric acid produces a dull yellow spot with a brown rim.

Shade R. gives somewhat different reactions. Dilute sulphuric acid turns the colour of the fibre bluer, which is partially restored by ammonia. Stannous chloride almost decolourises, while nitric acid produces a bright yellow spot with a brown rim.

*Indazine M.* (this Journal, 1889, 280) dissolves in water with a violet colour, which is not changed by either dilute sulphuric acid or ammonia. The solution is turned bluer on the addition of stannous chloride, and yields with bichromate of potash a black precipitate. Indazine is best applied on wool in a bath slightly acidulated with sulphuric acid, yielding blues somewhat like those obtained with the indulines in shade, which may not find much application as self-colours, but will be found useful in mixed shades. Indazine dyed on wool is turned redder by light; hot soap solution discharges the greater part of the colour.

When dyed on wool, indazine gives the following reactions:—Dilute sulphuric acid turns it bluer, but the colour is restored by ammonia. The colour is almost completely discharged by stannous chloride. Strong sulphuric acid turns the fibre green, and nitric acid produces a brown spot with a dark green rim.

*Patent Blue.*—This colouring matter comes into commerce in five different shades, in the form of blue powders, which would appear (according to Germ. Pat. 46,384, 1888) to be derivatives of meta-hydroxydiamidotriphenylmethane.

The leuco-bases of these colouring matters are obtained by the condensation of meta-nitrobenzaldehyde with tertiary amines, reducing the nitro compounds thus formed to amidotetra-alkyldiamidotriphenylmethanes, and transforming the latter by means of nitrous acid into the corresponding hydroxy compounds. They may also be formed directly by the condensation of meta-hydroxybenzaldehyde with tertiary aromatic amines. The hydroxy leuco-bases obtained by either of these methods are transformed into the corresponding colouring matters by oxidation in dilute acid solution with peroxide of lead or manganese.

Sulphonated dyes may be prepared by sulphonating the hydroxy leuco-bases and oxidising the lime salts of the sulphonic acids with peroxides and the theoretical quantity of acid.

Patent blue dissolves in water with a peacock-blue colour, which is turned to a yellowish-olive on the addition of dilute sulphuric acid; while ammonia has no action.

On wool, patent blue produces beautiful green shades of blue, which are remarkable, not only for their beauty, but principally for their fastness (compared with other triphenylmethane derivatives) to light and soap. The patterns which the author exposed to light were only slightly dulled after a month's exposure, and towards soap showed themselves very much superior to indigo extract.

Dyed on wool, Patent blue gives the following reactions:—Dilute sulphuric acid turns the fibre green; the original colour is partially restored by ammonia. Nitric acid produces a bright yellow spot with a green rim. Strong sulphuric acid turns the wool green and, on standing, yellow.

*Azo-carmin* appears to be a sparingly soluble azo dye which comes into commerce as a red orange paste, soluble with an intense magenta colour in ammonia. The colour is reprecipitated on acidulating with dilute sulphuric acid. In concentrated sulphuric acid it dissolves with an intense

emerald green colour. It is dyed on wool in an acid bath, and yields shades similar to acid magenta, but much faster to light, and especially to soap. It is useful in the production of compound shades.

(b.) *Adjective Dyes*.—Several new alizarin colours have recently been brought out which appear to be formed from ordinary Alizarin blue, by treatment with concentrated or fuming sulphuric acid. Nothing has, however, been published so far on the composition of these new products.

*Alizarin Green*, S.W. comes into commerce as a thick orange-brown liquid, soluble in water with a brown colour. Dilute sulphuric acid produces a dark green precipitate on boiling, and leaves the liquid light red, which becomes blue on addition of ammonia. Caustic soda produces a dark blue solution in the cold, but on boiling a dark green precipitate is formed. Stannous chloride gives a violet precipitate.

On wool, mordanted with bichromate of potash and tartar, Alizarin green yields a somewhat dull and not very intense shade of blue-green which is useful in certain compound shades.

Dyed on wool, Alizarin green gives the following reactions:—Dilute sulphuric acid removes at the boil some of the colour; ammonia turns it greener. Stannous chloride turns the colour to a light dull violet. Stannite of soda (stannous chloride dissolved in excess of caustic soda) produces a dull violet, but on washing and exposing to the air the original colour is restored. Strong sulphuric acid turns the colour blue, and nitric acid produces a yellow spot with dull violet border.

*Alizarin Indigo-blue*.—This colour comes into commerce as a thick red-brown liquid, in two shades, which are distinguished by the marks S.W. and S.M.W. The mark S.M.W. gives the following reactions:—It dissolves in water with a brown-red colour. On the addition of dilute sulphuric acid and boiling, a dark blue precipitate is formed. Caustic soda turns the solution blue, stannous chloride violet.

Alizarin indigo-blue S.M.W. produces on wool, mordanted with bichromate of potash and tartar, a shade of blue which is probably the nearest approach to indigo which has hitherto been produced with alizarin colours. The shade undergoes no appreciable alteration under the influence of light or soap. The mark S.W. produces a greener shade.

Dyed on wool, Alizarin indigo blue S.M.W. gives the following reactions:—Boiled with dilute sulphuric acid, the liquid becomes light red, which is turned blue again on rendering alkaline with ammonia, the fibre turning slightly greener; some colour is dissolved off. Ammonia has no action. Stannous chloride turns the colour violet. Stannite of soda only partially removes the colour; the solution is light violet. Nitric acid gives a brown spot with a small yellow centre. Strong sulphuric acid turns the fibre green. The reactions shown by the S.W. shade were similar, except that stannous chloride was without action, and strong sulphuric acid gave a light blue.

*Alizarin Yellow*.—Several shades of this dye are in the market, but only two will be described here. Alizarin yellow would appear from its behaviour to be an insoluble azo dye. The shade marked R.W. forms an orange-coloured paste, sparingly soluble in water, but easily soluble in caustic soda with a deep orange-red colour, from which solution the colour is precipitated on the addition of an acid. Stannite of soda turns the alkaline solution brown. This shade produces on wool mordanted with bichromate of potash and tartar an orange somewhat similar to Alizarin orange in shade, but brighter. It is not very fast to light, but stands soaping fairly well.

The Alizarin yellow G.G.W. is a yellow paste, sparingly soluble in water, but easily soluble in caustic soda with a yellow colour. Stannite of soda has apparently no action on the alkaline solution. On a chrome mordant this shade yields on wool a yellow somewhat similar to fastie, but not so fast to light.

When dyed on wool, the Alizarin yellows are turned light yellow by dilute sulphuric acid, the colour being partially restored by ammonia. Stannous chloride turns the fibre

light yellow. Strong sulphuric acid turns the fibre more orange. The most characteristic reaction is that with nitric acid, which produces a yellow spot with a broad scarlet rim.

## 2. DYES USED PRINCIPALLY FOR COTTON.

(a.) *Substantive Dyes*.—*Carbazol Yellow*.—This colouring matter is produced by the action of 2 molecules of salicylic acid on tetrazo carbazol. The commercial product dissolves in water with a dark orange colour. Dilute sulphuric acid produces an olive green precipitate. Ammonia renders the colour of the solution a little brighter. Bichromate of potash turns the solution brown.

Carbazol yellow dyes cotton in an alkaline bath yellow. On wool mordanted with bichromate of potash it yields shades similar to those obtained with fastie, but they are not so fast to light as the latter. Dyed on the fibre, Carbazol yellow gives the following reactions:—Dilute sulphuric acid gives an olive green, which is partially restored to the original colour by ammonia. Nitric acid produces an orange spot with a dark blue rim. Strong sulphuric acid turns the fibre dark blue.

*Cotton Yellow G*. dissolves in water with a dirty orange colour. Dilute sulphuric acid produces a red brown precipitate. Caustic soda renders the aqueous solution more orange.

On cotton this colour produces a canary yellow in an alkaline bath.

In this dyed state, cotton yellow is turned greener by boiling with dilute sulphuric acid, the colour being partially restored by ammonia. Nitric acid produces a brown spot with a violet rim.

*Mikado Orange 4 R*. dissolves in water with an orange colour. Dilute sulphuric acid turns the colour to an olive yellow; ammonia has no action. In strong sulphuric acid it dissolves with a pure blue colour.

Mikado orange dyes cotton in a neutral or slightly acidulated bath a fiery orange. It shows at the same time very little affinity for the animal fibres. Thus, when cotton and wool are immersed in the same bath acidulated with sulphuric acid, the shade produced on the cotton is much more intense than that produced on the wool.

Mikado orange is formed by the action of glycerol on paranitrotoluene sulphonic acid.

*Mikado Orange G*. and *Mikado Brown*, judging from their behaviour towards strong sulphuric acid, appear to be mixtures.

*Erika* dissolves in water with a pink colour, which is not changed by dilute sulphuric acid or ammonia. Stannous chloride produces a red precipitate. On unmordanted cotton, Erika produces a magnificent pink in an alkaline bath.

Dyed on the fibre, Erika is turned red by dilute sulphuric acid; the original colour is restored by ammonia. Stannous chloride partially removes the colour. Nitric acid produces an orange spot. Strong sulphuric acid turns the fibre blue.

*Thioflavin S*. (see below under "Thioflavin T.") comes into commerce as a yellow powder readily soluble in water with a golden yellow colour. Dilute sulphuric acid produces an orange precipitate; ammonia is without action. Strong sulphuric acid dissolves it with a yellow colour with beautiful blue fluorescence.

Thioflavin S. is applied on cotton, like most of the other direct cotton dyes, in an alkaline bath (soap and soda or phosphate of soda), and produces a bright canary yellow. The bath is only partially exhausted, and should be kept.

(b.) *Adjective Dyes*.—*Thioflavin T*. is one of a class of new yellow dyestuffs, consisting of the ethylated or methylated derivatives of dehydrotoluidine (Dahl's thio-toluidine or primuline base). The portions insoluble in water which are formed are converted into Thioflavin S. by sulphonation.

Thioflavin T. comes into commerce as a yellow powder, which dissolves in water with a yellow, somewhat turbid colour. Sulphuric acid clears the turbidity and renders the solution light yellow. Ammonia produces a light yellow precipitate; likewise tannic acid in presence of sodium acetate.

Wool is dyed in a neutral bath, silk in a bath with Marseilles soap. The shades produced on silk are very bright, and show a decided greenish tint. Cotton is previously mordanted with tannic acid and tartar emetic. Very bright yellows are obtained on cotton, which are said to stand light well.

Report No. II. Jour. Soc. Dyers and Colourists, 1889, 170-171.

### 1. DYES USED PRINCIPALLY FOR WOOL AND SILK.

(a.) *Substantive Dyes.*—*Roxamine.*—This dye comes into commerce as a dark brick-red powder, easily soluble in water, with a scarlet colour. The addition of dilute sulphuric acid to the aqueous solution causes no change, but the colour is turned much bluer on the addition of ammonia. In strong sulphuric acid the dye dissolves with a violet colour.

Roxamine is dyed on wool with sulphuric acid and sulphate of soda, and produces a rich shade of scarlet. From its behaviour it appears to be an azo-dye, but it differs from most of the ordinary reds inasmuch as it dyes the wool thoroughly and evenly, while, at the same time, the bath is exhausted. The colour produced on wool is fast to light, but not to soap.

Dyed on wool, roxamine gives the following reactions:—Dilute sulphuric acid has no action. Boiling with dilute sodium carbonate strips the colour. Strong sulphuric acid produces a violet colour, and strong nitric acid an orange spot with a blue rim.

*Cyclamine.*—This colouring matter belongs to the eosin class, but contains sulphur as an essential constituent.

Its constitution is probably represented by the formula—

It comes into commerce as a powder which dissolves in water with a magenta colour without fluorescence. Dilute sulphuric acid completely throws down the free acid as a scarlet precipitate. Ammonia has no action. In strong sulphuric acid the dry colouring matter dissolves with an intense orange colouration. Zinc dust and ammonia completely decolourise the aqueous solution, which on exposure to the air gradually becomes pink, with a green fluorescence.

Cyclamine dyes wool or silk in a neutral bath, producing a beautiful, very blue shade of red, resembling that of the blossom of the ordinary wild *Cyclamen* (from which the name of the dye is presumably derived). The colour is not changed much in soaping, but, like most other eosins, it is not fast to light.

Dyed on wool Cyclamine changes to a light pink on boiling with dilute sulphuric acid, and its original colour is restored by ammonia, but, if boiled with the latter reagent, the colour is partially extracted. The fibre is turned orange-red by strong sulphuric acid, and strong nitric acid produces a light orange spot.

(b.) *Adjective Dyes.*—*Cloth brown* (red shade).—This is a claret-brown powder, soluble in water with an orange-red colour. The colouring matter is completely thrown down by dilute sulphuric acid as a scarlet precipitate. Ammonia has no action. Stannite of soda decolourises it. In strong sulphuric acid the dry powder dissolves with an intense reddish-violet colour.

*Cloth brown* dyes wool directly in a bath acidulated with sulphuric acid, but the makers recommend that the material should be previously mordanted with 3 per cent. of bichromate of potash, and 1 per cent. of sulphuric acid, and that, in dyeing, acetic acid should be added to the dye-bath. In this manner bright brick-red shades are obtained.

Dyed on wool with a chrome mordant, *Cloth brown* is turned somewhat lighter on boiling with dilute sulphuric acid. The colour bleeds slightly in dilute sodium carbonate. By strong sulphuric acid it is turned dark violet, and strong nitric acid produces a brown spot with a black rim.

*Cloth brown* (yellow shade) comes into commerce as a black powder, which is soluble in water with a dark brown colour. It is completely precipitated by dilute sulphuric acid. Ammonia has no action, and stannite of soda decolourises it. Bichromate of potash occasions a light brown precipitate. In strong sulphuric acid the dye dissolves with a dull reddish-violet colour.

*Cloth brown* (yellow shade) is dyed on wool like the red shade, and produces on a chrome mordant a snuff-brown.

On wool the colour thus produced is very little affected by boiling with dilute sulphuric acid, and not at all by dilute sodium carbonate. Strong sulphuric acid turns the fibre dark violet, and strong nitric acid produces a brown spot with a violet rim.

*Cloth orange* forms a light chocolate powder, soluble in water with an orange colour. It is completely thrown down from the aqueous solution by dilute sulphuric acid, as an orange precipitate, whilst ammonia has no action. Stannite of soda decolourises the aqueous solution, and bichromate of potash produces in it an orange precipitate. In strong sulphuric acid it dissolves with an intense reddish-violet.

*Cloth orange* is dyed on wool like the *Cloth brown*, and produces on a chrome mordant a dull orange (brighter, however, than Alizarin orange).

The dyed fibre is not changed by boiling with dilute sulphuric acid, but in boiling dilute soda solution it bleeds slightly, with a yellow colour. Strong sulphuric acid colours the fibre violet, while strong nitric acid produces a brown spot with a black rim.

*Cloth orange* and the two shades of *Cloth brown* are all nitrogenous compounds, and judging from their general behaviour belong to that class of coal-tar colours which are generally known as the "benzidine colours," but which might more appropriately be termed "direct cotton dyes." Indeed, although the *Cloth browns* do not give good colours on cotton, the author obtained an exceedingly fine shade of orange on cotton by dyeing it with soap and soda in 5 per cent. of *Cloth orange*. On wool, the colours obtained appeared at first somewhat uneven, but, after soaping well for about 15 minutes in a 1 per cent. soap solution at 60°, they became perfectly even, and possessed a full appearance. This mode of application renders them suitable for remixing with other adjective dyestuffs. Unfortunately, they are not very fast to light.

*Gallamine Blue.*—This colouring matter comes into commerce as a dirty green paste, and is formed by the action of gallaminic acid on nitrosodimethylamine. This paste is slightly soluble in boiling water with a blue colour. In dilute sulphuric acid it is somewhat more soluble with a red colour, while in ammonia it dissolves easily with a violet colour. In strong sulphuric acid the dried and powdered paste dissolves with a red colour, which in thin layers appears dirty green (dichroic).

Gallamine blue produces on wool, mordanted with chrome and tartar, a blue which somewhat resembles in shade that obtained with Galloeyanin, with which Gallamine blue is indeed closely related in its chemical composition. The colour produced is partly discharged by soap.

For printing on calico the following recipe is given:—The colour is made up with 10 litres Gallamine blue paste, 18 litres thickening, 4 litres chromium acetate (15° B.), and 1 litre magnesium acetate (15° B.). After printing, steam 1½ hours and wash.

Gallamine blue dyed on wool gives the following reactions:—When boiled with dilute sulphuric acid it is almost completely removed with a violet colour. Boiling with dilute sodium carbonate also removes the greater part of the colour. Strong sulphuric acid produces no change, while strong nitric acid produces a light brown spot.

It is not probable that Gallamine blue will meet with an extended application as a self-colour, but it may be found useful in mixtures.

### 2. DYES USED PRINCIPALLY FOR COTTON.

(a.) *Substantive Dyes.*—*Diamine Yellow.*—This dye comes into commerce as a dark orange paste, soluble in water with an orange colour. Dilute sulphuric acid produces a brown precipitate, ammonia no change in the aqueous

solution. The dried paste dissolves in strong sulphuric acid with a red-violet colour.

Diamine yellow, like Diamine red and Diamine blue, is a direct cotton dye, and is applied like most of the others, viz., in a concentrated vat rendered alkaline with soap and phosphate of soda, or soap and soda, or some other alkali. It produces a shade of yellow something like Chrysamine, which is rendered duller by boiling with dilute sulphuric acid, whilst sodium carbonate turns it orange. Concentrated sulphuric acid turns the fibre red-violet, and strong nitric acid produces a violet spot, which is lighter in the centre.

*Diamine Red N.* forms a red-brown powder soluble in water with an orange-brown colour. Dilute sulphuric acid produces a violet-black precipitate; ammonia is without action. In strong sulphuric acid the dye dissolves with a pure blue colour.

Diamine red N yields on cotton a full shade of red, which is turned by dilute sulphuric acid to a dull violet. Sodium carbonate restores the colour. Strong sulphuric acid turns the fibre blue, and strong nitric acid produces a light-coloured spot with a drab rim.

*Diamine Blue B.* comes into commerce as a brown-black powder soluble in water with a violet colour. Dilute sulphuric acid produces in the aqueous solution a bright blue precipitate, while ammonia turns it crimson. In concentrated sulphuric acid Diamine blue B. dissolves with a blue colour.

Dyed in the ordinary way on cotton, Diamine blue B. yields a somewhat reddish shade of blue, which remains unchanged when boiled with dilute sulphuric acid. Ammonia dissolves some of the colour off, the solution being light red, while the fibre is turned violet. Strong sulphuric acid turns the fibre blue, and strong nitric acid produces a flesh-coloured spot.

*Sulphone-azurin*, another direct cotton dye, comes into commerce as an indigo-blue powder, which in its reactions differs essentially from those already in the market. Even in boiling water it is only sparingly soluble. Dilute sulphuric acid turns the aqueous solution to a red-blue, which on boiling becomes red-violet. Ammonia produces no change in the cold, but the solution becomes redder on boiling. The aqueous solution is decolourised by boiling with stannite of soda. In strong sulphuric acid it dissolves with a crimson colour.

Sulphone-azurin is dyed on cotton in an alkaline bath, and produces the greenest shade of blue which has hitherto been obtained with the direct dyes.

On the fibre it is turned redder by boiling with dilute sulphuric acid; the original colour is restored by sodium carbonate. Strong sulphuric acid turns the fibre violet, and nitric acid produces a flesh-coloured spot.

(b.) *Adjective Dyes.*—*Indoline.*—This is a derivative of nitrosodimethylamine, and is formed by the action of nitrosodimethylamine on  $\beta$ -naphthol. The commercial product is the zinc chloride double salt with the chloride of the base. The same product has been in the market for some years under the name of *New blue*, or *Meldola's blue*. It is dyed on cotton mordanted with tannin and tartar emetic, or tannin and iron, and produces indigo-blue shades which are remarkable on account of their great fastness. Perhaps the greatest drawback which has attended the use of this colouring matter is the fact that its dust has such a violent action on the mucous membranes, causing sneezing and coughing when inhaled even in minute quantities. This drawback has now been overcome by a continental firm, which produces the colouring matter, not in powder, but in the form of well-defined crystals, under the name of *New blue crystals*.

*Chrome Violet.*—This colouring matter, which is used only in printing, is the ammonium salt of aurin tricarboxylic acid. It forms a reddish chocolate powder, soluble in water with a deep red colour, which is turned light brown by ammonia. Dilute sulphuric acid completely precipitates the colour. In strong sulphuric acid it dissolves with a brown colour. Chrome violet is printed on calico with thickening and chromium acetate, and the colour is developed by steaming. It is useful for mixtures.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

*Oxycellulose.* E. Noeltzing. *Färb. Zeit.* 1889 (2).

By the action of oxidising agents on cellulose (cotton), products of oxidation are formed which have been called oxycellulose. This name is, however, given in common to two products, different in their nature, namely, the oxycellulose of Witz, and that of Cross and Bevan. In the *Bulletin de la Soc. Ind. de Rouen*, Witz has published the results of extensive and very interesting researches on the mode of formation and preparation of his oxycellulose. It is formed by the reaction of almost all oxidising agents: chlorine, acids of chlorine, chromic acid, dilute nitric acid, &c., on cotton. Thus the strength and power of resistance of the fibre is, on the one hand, considerably diminished, especially when the cotton, after oxidation, is treated with alkali or soap, whilst on the other hand the affinity of the fibre to basic colouring matters is increased to some extent, but it is lessened considerably for the sour and direct azo-colouring matters. The colourist is but too frequently disappointed in the results attained with material which has become attacked so as to form oxycellulose.

In the practice of printing, such an attack of the cloth is, however, observed not only under the influence of oxidising agents, but also under that of acids and sour salts. This is owing to the formation of the so-called *hydrocellulose*, the properties of which have been studied by Aimé Girard. Hydrocellulose does not possess the property of fixing basic colouring matters directly. In many instances, such as in the reaction of sour oxidising agents, the formation of oxy- and hydrocellulose possibly takes place simultaneously.

Under the name of oxycellulose Cross and Bevan have described a product that seems not to be identical with that of Witz. This "oxycellulose" is obtained by treating cotton on the water bath with nitric acid of 50 per cent., washing, dissolving in alkali, and reprecipitating with acid, a solution of salt, or with alcohol. The "oxycellulose" thus obtained does not possess the property of being dyed by basic colouring matters, either directly or after solution in alkali and reprecipitation.

The nitrocellulose obtained by the reaction of concentrated nitric acid or nitrosulphuric acid on cotton in the cold has, like the oxycellulose of Witz, the property of attracting basic colouring matters. The same is the case, as might be expected, with celluloid (a compressed mixture of gum-cotton and camphor); also the reaction products of sulphuric acid on cellulose, amyloid, and parchment paper are dyed in a similar manner.

Cellulose is not modified by dissolving in an ammoniacal copper solution and subsequent precipitation; the precipitated substance does not attract basic colouring matters, nor is there any oxycellulose formed in the preparation of pure cellulose by Hugo Müller's method (alternate treatment of the raw fibre with bromine water and ammonia).

Common bleached cotton shows a weak, but imperceptible, attraction to basic colouring matters. This is owing to traces of oxycellulose being formed in the treatment with chloride of lime. Hence cotton which is to be dyed with direct azo-colouring matters is not chlorinated.

*Mercerised* cotton attracts but very little. But if caustic soda, even in a very dilute state, is caused to act on cotton at an elevated temperature, and in the presence of air, the fibre is considerably weakened, and then attracts basic colouring matters. By the reaction of alkali, therefore, oxycellulose is formed, and not hydrocellulose as in the reaction with hydrochloric acid.

*On the Prevention of Stripiness in Woollen Stuffs Dyed in the Piece.* Otto Walther. *Färb. Zeit.* 1889 (2).

It has been proved by practical experience, that in consequence of the various manipulations to be applied to woollen stuffs, such as washing, pressing, wringing, hanging on rods, treatment in the hydro-extractor, &c., all the impurities of an oily or different nature are found in most cases to be unequally distributed, and that, consequently,

when dyeing the pieces, an equal attraction of the colouring matter cannot possibly take place. In fact the fundamental rule is too frequently neglected, namely, that every material intended for dyeing should be carefully cleaned and be subjected to the process of dyeing only in a clear state and without blemish. For wool in the flock, such an exquisite purity is apparently less necessary, at least as far as regards unequal dyeing, because the unequally dyed portions are so thoroughly mixed in the course of manufacture, by spinning and weaving, that at most the intended shade can only suffer a slight deviation. Now, it is the unanimous opinion of all authorities in the woollen industry, that to obtain perfectly pure stuffs a clean washing of the wool is an unconditional requirement, and hence the conclusion is absolute that wool intended for cloth to be dyed in the piece should be submitted to a most thoroughly and carefully conducted process of washing. There is nothing that favours more the occurrence of impurities in yarns and stuffs than the residue of wool fat adhering to the woollen fibre, and yarns and stuffs manufactured; wool badly cleaned of fat will never turn out quite pure, or at least not as pure as is necessary for a uniform appearance of the colours in the piece. It might be objected that very many yarns, and even cloths, are manufactured from unwashed wool, and were afterwards washed perfectly clean. But it should be observed that this is done mostly with inferior materials, and even then never for finer cloths.

A further circumstance, accounting partly for the more frequent occurrence of unequal colouring at the present time, is that a great part, if not the whole, of the wools now used for manufacture show a character different as to many points from that of the wool material of former times. This characteristic difference may be distinctly observed by anyone who, in addition to home-grown wools (formerly used exclusively), also manufactures with colonial wools. Thus the transmarine wools, especially those from the Cape, always have a greasy feel which cannot be removed even by the most thorough washing. This greasiness is either absent altogether in native wools, or possessed by them only to a very small extent. The occurrence of "stripiness" in such dyed wools is doubtless in great measure due to the fact just referred to. The fibre retains this property throughout all the stages of the manufacture, and thus it happens that also the yarns or cloths show little adhesion to water, and imbibe it with difficulty, whilst they as rapidly lose the quantity imbibed. Of course such greasy cloth works badly in the dye-bath, for the dye-liquor fills and penetrates the more wetted parts of the cloth or yarn far more rapidly than the others.

The defective purity of most washed Cape wools is the consequence of irrational treatment in washing, and the peculiarly greasy consistency natural to the fibre of those wools. It should, therefore, be made a rule that washed Cape wools should, before manufacture, be subjected to a thorough and most careful washing, *i.e.*, on the backs of the animals, care being taken as far as possible to avoid felting the wool. The chemical operation of removing the burrs, by means of acid and heat, the so-called "carbonising" applied to at least 50 per cent. of all woollen cloths dyed in the piece, contributes in no small measure to make the intricate and frequently quite unaccountable phenomena in dyeing, milling, and washing still more complicated. After the process of carbonisation a salt or this along with some acid, may be left behind in some cases, adhering to the fibre, and so much the firmer the more this fibre is contaminated with natural grease or other matters of greasy nature.

In consequence of the treatment in boiling water wool loses some of its elasticity and property of felting, and because both these qualities are desirable in spinning and fulling, it is better that the ready and dressed goods be subjected to the process of boiling, a practice which the author in most cases follows. If there be any suspicion about the purity of the goods a small quantity of potash may be added; if necessary this may also be done during the boiling. Where elasticity and faculty of felting are of less consideration it is still advisable to boil the wool before spinning, in order to a more complete purification of the goods from oil, soap, &c. The pieces, or even the yarns,

may before dyeing be effectually subjected to the same treatment. The chief point is that the wool, as well as the fabrics or yarns, shall be thoroughly rinsed immediately after boiling, when still warm, so that the dissolved substances may be removed before they again coagulate on the fibre.

Cloths are brought to the washing machine directly from the vat or the boiler, and rinsed clear after addition of fuller's earth, or they are brought from the boiling vat into a second vat filled with pure water that can be renewed from time to time. This second vat contains two pairs of squeezing rollers—one horizontal, the other vertical—close together, through which pieces sewed together to form an endless band are caused to pass until they are perfectly clean; that is, until they have lost their slippery feel. Instead of the two pairs of rollers a single horizontal pair may be mounted for the whole breadth of the cloth; but in this case the cylinders should be made to fit well, and so that they will not turn awry; one of them should also be covered with caoutchouc. For the same purpose the broad-washing machine, constructed by Hemmer, in Aix la Chappelle, may be employed, with the additional advantage that the washing may be done with fuller's earth, which is preferable to the simple squeezing and rinsing in the vat. Finer stuffs which have to undergo the finishing before the dyeing process, are boiled best before the finishing. This prevents the impurities from being fixed too firmly on the fibre by the finishing. For the preservation of the nap the goods may also be wound loosely on wooden cylinders, but should then, before cooling down on the cylinders, be immediately beamed off and brought still warm on the washing machine. With a view to a thorough cleansing, the boiling in an open boiler is, however, to be preferred. If this operation be carried out correctly, it will be found that the colours obtained are brighter and fuller, and that, besides, there is a saving in dyestuff. With unboiled goods, part of the colouring matter is lost through rinsing, in consequence of its being fixed less firmly on the fibre, so that the shade has frequently to be made somewhat deeper.

The chemicals used for carbonising and neutralising will now adhere to the fibre so much the less, the better the material has become freed from oil, soap, and alkalis. Their deteriorating effect in piece dyeing is, therefore, partially prevented. In consideration of the manifold complications arising from combinations between the residues of the acid or the neutralising substances with the soap applied to the wool, it is advisable to carbonise the cloths after fulling. This, however, is possible only with those kinds of material which, after fulling have still to undergo some mechanical process, such as raising or pressing, &c., as mechanical aid in the removal of the carbonised organic remains of vegetable origin cannot be well dispensed with.

#### *The Recovery of Tin in Dyeing* M. Martinon. *Ann. de la Soc. des Sciences Ind. de Lyon.*

THE weighting of silk with bichloride of tin is effected by immersing it in a solution of variable strength, but generally averaging from 20 to 28 B.

When the silk is well impregnated with this solution, it is wrung out, and, in order to get rid of the greater part of the bichloride, it may either be pressed in a special machine, which extracts only a small quantity of the liquid, or be hydro-extracted, the inside of the hydro-extractor being lined with lead, or covered with gutta-percha or hardened caoutchouc.

The silk is next washed in clean water, passed through carbonate of soda, and either soaped, or put again into the bath of bichloride of tin.

The following results follow from the washing of the silk.

The bichloride absorbed by the silk is decomposed at first partially, and afterwards entirely, and more or less rapidly, according to the proportions of the silk and water brought into contact. A certain quantity of the oxide of tin resulting from this decomposition remains fixed upon the silk, the rest spreads through the bath; it is the latter quantity that has hitherto been lost, and for the recovery of which the method to be described has been recently devised.

The first wash-waters of the silk are run into a large reservoir, and immediately after milk of lime is added to saturate the free hydrochloric acid, and to facilitate the deposition of the oxide of tin, the mixture being meanwhile agitated. Agitation by a current of air with a Koerting injector gives very good results. For the precipitation of this oxide of tin other bodies besides lime may be employed, such as the alkaline carbonates or alkaline earths. Tannin, which is often a residue in dye-houses, sulphuric acid even, and many other bodies can effect this precipitation.

For the proper treatment of these wash-waters there are required at least two reservoirs of suitable capacity. Whilst the liquid of one is being decanted, the other may be filled.

When the deposit has accumulated sufficiently, which takes place quickly enough if sufficient lime be used, and if the stirring be properly performed, the clear liquid is drawn off, and the precipitate thrown on to a series of filter beds.

This filtration of the oxide of tin takes place very slowly, and even after 24 hours only a paste containing 15 per cent. is obtained. This white paste may be treated in several ways.

It may be converted directly into bichloride, or reduced to the metallic state by well-known metallurgical processes. Whatever plan is adopted, the additional outlay is soon covered by the profit realised.

Thirty to 40 per cent. of the tin used may thus be recovered, and already the method is in operation in almost all the dye-houses at Lyons and at several other manufacturing centres.

The soap baths used in the soaping or boiling of the silk weighted with bichloride of tin are treated in exactly the same way; these deposits contain tin partially combined with fatty acids, the oxide of tin absorbed by the silk in its passage through these baths.

The deposits in the baths of catechu and of tin salts used in black dyeing may be treated similarly for the recovery of tin by metallurgical processes. The application of these processes furnishes at Lyons from 6 to 7 kilos. of metallic tin per month.

*The Chroming of Wool.* E. Knecht and A. Ward. Jour. Soc. Dyers and Colourists, 1889, 184-185.

A SERIES of experiments previously carried out by Messrs. P. Kay and E. Bastow with the author was published in a paper entitled "The Fixation of Chromium by the Wool Fibre."

The conclusions drawn from the results obtained were briefly as follows:—

1. The amount of chromium fixed by the wool fibre in mordanting with bichromate of potash varies with the concentration of the solution. When sulphuric acid is used along with the bichromate, the amount fixed is considerably greater. In mordanting with 3 per cent. of bichromate (the amount usually employed on the large scale) only about 1 per cent. is fixed by the wool.

2. In using pure bichromate of soda equivalent to 3 per cent. of bichromate of potash, a larger proportion of chromium is fixed than in the case of the potash salt, which might in some measure account for the different results obtained by practical dyers with these two mordants.

3. The addition of tartar to the mordant solution has no material influence on the amount of chromium fixed.

4. The amount of chromium fixed from chrome alum is about twice as great as that fixed from an equivalent percentage of bichromate. In this case the chromium is probably not so intimately combined with the fibre as when bichromate has been used as a mordant; besides, it here plays the part of a base, while in the latter case it plays the part of an acid.

5. In mordanting with bichromate of potash the amount of chromium fixed by the fibre is directly proportional to the time of immersion and to the temperature of the mordanting bath.

6. The fixation of chromium by wool in mordanting with potassium bichromate is always accompanied by a partial decomposition of the bath into chromate and chromic acid. Although the reaction is not a quantitative one, and is accompanied by a certain amount of mechanical absorption,

it seems probable that the keratine, or substance, of the wool plays here the part of a base, which forms with chromic acid an insoluble or sparingly soluble chromate.

7. In the practical working of a bichromate bath, the amount of chromium contained in the bath must necessarily increase according to the number of times the bath has been used. Thus if 3 per cent. of bichromate are used in the first bath, 1 per cent. is absorbed by the wool, 2 per cent. remaining in solution. On adding 3 per cent. for the second bath, we have a total of 5 per cent. bichromate in solution. If we now assume that 1 per cent. of this is again absorbed in mordanting the second lot of wool, we shall have left in solution after chroming for the second time an equivalent equal to  $5 - \frac{5}{3} = 3\frac{1}{3}$  per cent. bichromate of potash, so that in making up again with 3 per cent. for the third mordanting bath we shall actually have an equivalent to  $6\frac{1}{3}$  per cent. bichromate of potash. In this manner the bath must necessarily become more and more concentrated until it has ultimately to be thrown out, and large quantities of bichromate are thus inevitably lost every day. Theoretically (and this is the most important practical issue of our experiments) the only rational way of chroming on an economical scale would be to use 3 or 4 per cent. of bichromate for the first bath, and then add to each consecutive bath just as much fresh bichromate as has been absorbed by the wool (about 1 per cent.) along with a sufficient quantity of sulphuric acid to convert the chromate formed, into bichloride again.

8. If we take the amount of chromium fixed by the fibre as a guide for the efficiency of the mordant, then by far the best chromium mordant for wool would be chromic acid. Next in value comes bichromate of potash and sulphuric acid, then bichromate of potash alone, and lastly chromate of potash.

#### ECONOMY IN THE USE OF CHROME.

The chief object of the present investigation was to confirm by experiments, carried out on the large scale, to what extent the percentage of chromic acid, as well as the alkalinity of a chrome bath, increased after continued use.

The experiments were performed on liquors which had been used for chroming Botany slubbing. There were nine slots of slubbing chromed before a liquor was run off down the drain.

In the following, No. 1 liquor represents the liquor left in the cistern after the first panful of wool had been chromed; No. 2 liquor, the liquor left in the cistern after the second panful of wool had been chromed; and so on, up to No. 9 liquor. The chrome used was crystallised bichromate of soda.

For the 1st panful 5.6 per cent. of chrome for the weight of wool was used.

For the 2nd panful 4.4 per cent. of chrome for the weight of wool was used.

For the 3rd panful 4.4 per cent. of chrome for the weight of wool was used.

For the 4th panful 4.4 per cent. of chrome for the weight of wool was used.

For the 5th to 9th panfuls 4.0 per cent. of chrome for the weight of wool was used.

First, the total amount of chromic acid was estimated in the nine liquors by means of ferrous ammonium sulphate. In each case three titrations were made, and the figures were calculated from the mean of the three. The following figures were obtained:—

100 LB. WOOL to 630 GALS.

Pounds in 630 Galls. abstr.	Per Cent. $K_2Cr_2O_7$		Grms.	Difference.
4.21	1.36	No. 1 liquor contains 0.6567 $CrO_3$ per litre		..
5.73	2.91	No. 2	0.9168	0.2541
7.27	2.86	No. 3	1.1550	0.2442
8.68	2.89	No. 4	1.3629	0.2079
9.52	3.16	No. 5	1.5114	0.1485
10.31	3.21	No. 6	1.6368	0.1254
11.23	3.08	No. 7	1.7829	0.1452
12.37	2.86	No. 8	1.9635	0.1815
13.6	2.77	No. 9	2.1582	0.1747

Although these figures do not coincide exactly with those obtained by experimenting on the small scale, they are, nevertheless, analogous, and are of sufficient interest to woollen and worsted dyers, inasmuch as they show that in running off of an old chrome bath a considerable quantity of the mordant is lost.

That the bichromate is actually converted into chromate in working on the large scale is proved by the following estimations, made with laemoid as indicator, with the same liquors as those already referred to:—

Liquor required for the conversion of the chromate formed into bichromate.

No. 1 liquor, per litre	0.0980	grms. sulphuric acid.
No. 2     "     "     "	0.2009	"     "     "
No. 3     "     "     "	0.2949	"     "     "
No. 4     "     "     "	0.3773	"     "     "
No. 5     "     "     "	0.4655	"     "     "
No. 6     "     "     "	0.5488	"     "     "
No. 7     "     "     "	0.6027	"     "     "
No. 8     "     "     "	0.6713	"     "     "
No. 9     "     "     "	0.6909	"     "     "

From these latter results it cannot only be shown to what extent the alkalinity of the mordanting solution increases, but also in the following table the relative proportions of chromate and bichromate left in solution after each operation, in grms. per litre:—

—	Total $\text{CrO}_3$ .	$\text{CrO}_3$ as Chromate.	$\text{CrO}_3$ as Bichromate.
No. 1 .....	0.6567	0.2008	0.4559
No. 2 .....	0.9108	0.4116	0.4992
No. 3 .....	1.1550	0.6924	0.5526
No. 4 .....	1.3629	0.7730	0.5899
No. 5 .....	1.5114	0.9338	0.5776
No. 6 .....	1.6368	1.1244	0.5124
No. 7 .....	1.7820	1.2349	0.5471
No. 8 .....	1.9635	1.3754	0.5881
No. 9 .....	2.1582	1.4156	0.7427

This table shows that, whereas the amount of bichromate left in solution remains about constant at 0.5 grm. per litre, the amount of chromate steadily increases until, when the bath has to be let off, it contains an equivalent of no less than about 3.237 grms. of crystallised bichromate of soda per litre. There are thus let off into the drains from a vat of, say, 800 galls. capacity, somewhat less than 26 lb. of chrome, and this must not only mean a loss to the dyer, but must also tend to pollute the watercourse to a very considerable extent.

But now that the disease has been pointed out a remedy must be also suggested, and, if possible, that remedy should be of the simplest kind. Such a remedy is the following:—

By adding to the second "hole-full" just that amount of sulphuric acid necessary to convert the chromate formed into bichromate—viz., 0.098 grm. of sulphuric acid per litre of liquid in the bath, it would be brought back to the same condition as it was in when started; and it would not be necessary to add to the second bath any more chrome than had combined with the fibre, viz., about 1 or  $\frac{1}{2}$  per cent. The same would have to be done with the third and subsequent baths. In this manner the vat could probably be got to work for a greater number of times in succession, and on letting off, say after the ninth time, the loss in chrome would be considerably less than one-half of what it is at present.

Practical experience has shown that a chrome bath works better after it has been used two or three times than when fresh. In this case—that is, if the dyer specially wishes to have his chrome bath alkaline—the same principle might be adopted, and the bath kept on the alkaline side till the end by only commencing to add the necessary amount of sulphuric acid after, say, the third hole-full. The loss in chrome on letting off would, indeed, be somewhat greater than if

sulphuric acid were used from the beginning; but there would, nevertheless, be a very considerable saving as compared with the process referred to.

In proposing this method there was no desire to suggest that every dyer would have to be able to analyse quantitatively the contents of his chrome vat. A much simpler remedy is at hand. He has only to add bichromate to the first three hole-fulls as usual, but for the fourth and subsequent hole-fulls he must use a mordant made up in solution, and containing besides the bichromate of potash or soda the necessary quantity of sulphuric acid to keep his subsequent baths of a standard strength.

Some dyers use sulphuric acid in chroming over and above the amount necessary to neutralise the alkalinity of the water, and thus practically chrome with a solution of chromic acid. To these cases the method of the authors does not apply. They are of opinion, however, that also by using excess of sulphuric acid the loss of chrome in letting off would be very considerably lessened.

*The Theory of Chroming.* E. Knecht. *Jour. Soc. Dyers and Colourists*, 1889, 186.

WHEN wool is boiled in a solution of bichromate of potash or bichromate of soda, it absorbs, as is well known, a certain proportion of chromium and becomes yellow. Now this absorption is not due, as is held by some chemists, to the simple mechanical absorption of unchanged bichromate, but is due, according to the opinion expressed two years ago by the author, to a splitting up of the bichromate molecule into chromate and chromic acid. The chromate remains in solution, while the chromic acid combines chemically with the substance or a constituent of the substance of the wool fibre to form an insoluble or sparingly-soluble yellow chromate. This will be inferred from the following observations:—

1. When wool is boiled in a weak solution of bichromate of potash, the colour turns from orange to yellow.

2. Wool dissolved in strong hydrochloric acid and then diluted with water gives with bichromate of potash a thick yellow precipitate. A similar precipitate is obtained with lanuginic acid, and it is probable that this precipitate is chemically closely allied to the insoluble compound produced on or in the wool-fibre in mordanting.

It has been argued that the formation of chromate in mordanting wool with bichromate is not due to the dissociation of the salt, but to the generation of ammonia from the wool-fibre. In order to test the correctness of this assertion, wool was boiled for an hour in a flask with water, and the gases given off were collected in another flask containing cold distilled water. All the ammonia which might have been produced must now be contained in the receiving flask; but on testing the liquid with Nessler's reagent we found it to contain only the merest trace of ammonia, less than one thousandth part of what would have been necessary to effect the chemical change referred to. It might further be argued against our theory that the neutralisation of the bichromate is due to the presence of alkaline salts in the wool-fibre. But this argument must also fall to the ground when the results of the following experiment are taken into consideration:—

Wool was first boiled with excess of dilute hydrochloric acid, for the purpose of removing any salts of the alkalis or alkaline earths. It was then boiled repeatedly in distilled water until no more traces of acid could be detected. Five grms. of the wool thus treated were now mordanted with 4 per cent. of bichromate of potash (0.2 grm.). The bichromate and chromate left in solution were estimated volumetrically, and the chromic acid absorbed by the wool by difference. The following results were noted:—

	Grms.
Total bichromate in solution.....	0.630
" chromate     "     "	0.112
Chromic acid in the wool .....	0.057
	<u>0.199</u>

This shows that the reaction is independent of any alkaline inorganic salts which may be contained in the wool.

Nietzki's assertion that in chroming wool the chromium is fixed as chromate of chromium requires proofs which are as yet not forthcoming. If the bichromate should be reduced to chromium chromate, the reaction would be attended by the formation of caustic alkali, and a very considerable oxidation of the fibre, as will be seen from the following equation:—

It is well known that chromed wool becomes oxidised when exposed to light; this is shown by the change in colour from yellow to green. But that such a powerful oxidation as that shown by the above equation should take place in the ordinary process of chroming seems highly improbable.

#### *A Simple Method of Producing "Green-Mordanted" Wool.* E. Knecht. Jour. Soc. Dyers and Colourists, 1889, 186—190.

In using the alizarin colours, as well as some of the other adjective colours, on a chrome mordant, it is generally desirable, indeed sometimes necessary, that the chromium should not be present on the fibre as chromic acid, but as chromic oxide. This result can be attained by mordanting with chrome alum or chromium fluoride; but the results are not good in the former case, while chromium fluoride, although yielding excellent results as a chrome mordant for wool, it is yet too expensive. The most usual way of obtaining "green-mordanted" wool is to use along with the chrome either tartar or oxalic acid. As the chromic acid becomes fixed on the fibre it is reduced to the green state at the expense of the tartaric or oxalic acid, which in their turn become more or less completely oxidised. This method has been found to give very good results in the hands of practical men, but the quantities of tartar and oxalic acid usually employed (2½ per cent. tartar, or 3 per cent. oxalic acid to 3 per cent. chrome) are not by any means sufficient to completely reduce the chromic acid on the fibre to chromic oxide.

At the same time the method for economising chrome which we mentioned in the first part of our paper could not be used, since the chrome bath becomes partially reduced by the presence of tartar, and this reduction would only be accelerated by the addition of sulphuric acid.

Now if wool mordanted in the usual way, either with bichromate alone, or with bichromate and sulphuric acid, be passed through a solution of bisulphite of soda or some similar reducing agent (but the bisulphite is the cheapest), the change from the yellow to the green very soon takes place. As the result of a number of experiments the author finds that it is best to chrome with 3 per cent. of bichromate and 1 per cent. sulphuric acid, or thereabouts, and reduce in a tepid or warm bath containing not more than about 5 per cent. of commercial bisulphite solution (sp. gr. 1·3).

Treated in this manner the chrome on the wool becomes more completely reduced than if tartar had been used in chroming. There is certainly the trouble of preparing a fresh bath, but the difference in price between the tartar and the bisulphite would compensate for this. Besides, the results obtained in dyeing are much better with a large number of adjective dyes, notably logwood, alizarin blue, cœrulein, and gallein.

In the discussion which followed, the President, Mr. Jas. Sharp, said he thought that 4 or 5 per cent. of "bichrome," referred to by Dr. Knecht, which was certainly a maximum amount, might probably be cut down to one-half and still give all the results necessary. If so, about half the bichrome at present used finds its way down the sewers. To produce brighter or more bloomy shades, a little sulphuric acid was now found an advantageous addition to the bichromate bath. Nevertheless, the use of sulphuric acid must be graduated with caution on the dye on the warp "will go." Sometimes tartar or oxalic acid is used with the bichrome.

Mr. A. H. Allen desired to know the action of normal chromate and bichromate upon laemoid, more especially which of these salts is neutral to laemoid and which is not.

He gathered that the point of strict neutrality to laemoid was at the formation of bichromate, the chromate neutral as to composition being alkaline as to reaction. (Confirmed by Dr. Knecht.) He considered it irrational to add tartarate to bichrome, and that people doing so got their fair results in spite of what they did, and those results would be better under more rational conditions. Was it a fact that so much bichromate was wasted?

Mr. Wilkinson, referring to the author's recommendation to add sulphuric acid after each batch of wool is taken out of the vat, said that when dyers mordant with bichrome, if they get it in the condition of chromic acid through the addition of sulphuric acid, the fibre becomes undoubtedly injured, and slubbing dyers in general preferred to keep on the side of the chromate than on that of the free chromic acid. That acid is also injurious to the colours, and its activity in their direction causes those colours to be taken up so greedily that uneven shades are the result. Not only is its action energetic on the fibre, but it is also exceedingly active on the colouring matter. In the loose wool trade, such as that of Huddersfield, it is a very different matter. A large amount of sulphuric acid is used there simply to neutralise the amount of alkali that is brought forward from the scouring, because less attention is paid to the scouring process. Here again he thought it would be well worth the attention of some chemist to obtain a knowledge of the amount of alkali which is usually left in the slubbing. The amount of alkali left behind in different works will be found to vary, and consequently the chromate or bichromate will be found to vary in the mordant bath. He thought it better indeed to keep nearer to chromate than bichromate. A good deal of trouble had been caused in some kinds of alizarin dyeing through too active bichrome baths.

Mr. Rawson said that in many dyehouses, to his knowledge, the slubbing or yarn is taken direct from the scouring bowls, without any washing with water, into the chrome bath. The consequence is that the alkali in the wool at once reduces the bichromate of potash to normal chromate, and it would therefore be impossible to calculate the amount of acid necessary to be added without taking this factor into consideration. The amount of alkali thus introduced into the chrome bath would often be much more than that formed by the boiling of the wool itself. In the experiments on the large scale it appears that about 3 per cent. of potassium bichromate was removed by each successive lot of wool. This includes the bichrome removed by washing; but he would very much like to know what amount was actually fixed on the fibre. It was scarcely likely that as much as 1 per cent. was removed by washing, so that in all probability, accepting the figures given, more than 2 per cent. was fixed. This was, comparatively, a large amount. The quantity of chromium fixed on the fibre was a most important matter in connexion with the fastness to light of logwood blues and blacks. If more than a certain amount was present, the black, in a short time, was most likely to turn green. In all cases of logwood blacks which had turned green an excess of chrome had been found according to his experience. It was difficult to state a limit, since much depended upon the condition in which it exists; but, in his opinion, not more than 1·5 per cent. of potassium bichromate should be fixed upon the fibre. Where the goods are chromed after dyeing as well as before (with the object of making the wool clean), there was no doubt that part of the chromium was often fixed on the fibre as chromate, or chromic acid, and such being the condition, the black was very liable to turn green. It was most probable that in after-chroming or finishing by the use of too much bichromate of potash, the logwood black was rendered liable to turn green. If chromic acid is deposited on the fibre in the first chroming, it is in all probability reduced to chromic oxide when it comes into the logwood bath. Both the author and speaker had made many experiments in connexion with the action of sodium bisulphite on chromed wool, and in all cases had found that the shades produced by logwood were not only deeper when the chromed wool had been thus reduced, but very much brighter. The effect was especially noticeable in light shades. The patterns produced were each mordanted with 3 per cent. of potassium bichromate and 1 per

cent. of sulphuric acid, and dyed with 10 per cent. of logwood. Of course, this amount of bichrome was too large for practical operations, but it was taken in order to show the effect of chromic acid and chromic oxide respectively with greater distinctness. One of the patterns, after mordanting, was treated with 5 per cent. of sodium bisulphite solution in the manner described by Dr. Knecht. The difference was very striking; the hank treated with bisulphite was of a bright, bloomy blue shade, whereas the other was a dull, dirty grey. This latter effect can only be attributed to the colouring matter of logwood being partially destroyed by the chromic acid on the fibre.

Mr. Frusher desired to know whether Dr. Knecht had made any experiments with wool previously bottomed with indigo. In chroming on indigo-bottomed wool they had a certain loss of indigo in the ordinary mordanting bath with bichromate, and with the addition of sulphuric acid there was an increased loss of indigo. He desired to know whether there would be any greater effect with the use of sulphuric acid than without?

In reply, Dr. Knecht said that the amount of chrome used for his experiments was between 4 and 5 per cent. The material to be chromed was Botany slubbing, a substance which absorbed considerably more than woven or spun material. Wool of that quality also absorbed more chrome than any other wool—English wools, for instance. He had shown that after they had mordanted wool in potassium bichromate the bath became alkaline. If they mordanted another lot of wool in the same bath it became still more alkaline, and if they mordanted further lots the alkalinity became increasingly great. He suggested the use of sulphuric acid to counteract that growing alkalinity, but did not either use or suggest the use of that amount of sulphuric acid necessary to render the bath acid. He kept it on the alkaline side. He only added a sufficient amount of sulphuric acid to bring the chromate back to bichromate. He had never tried to completely exhaust a bichrome bath, but thought it might be done. The author thought that in the case of, indigo-bottomed wool, chroming with sulphuric acid would be much more injurious than chrome alone.

Mr. Rawson considered that much chromium existed on the fibre after chroming, in the form of chromic acid, but that it was reduced to chromic oxide in the dye-bath at the expense of the colouring matter of the logwood. A portion of the colouring matter was not only destroyed and lost, but the decomposition products were apparently fixed to a certain extent on the material, and a dull grey instead of a bright blue was obtained. With an excess of colouring matter, no doubt this grey became merged and lost in the excess of deep black obtained. When indigo-dyed cloth was chromed, the shade became duller and greener, and certainly appeared to have lost indigo.

#### PATENTS.

*Improvements in Dyeing Cotton or other Vegetable Fibres with Blended Colours.* J. Imray, London. From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, Paris, France. Eng. Pat. 18,010, December 10, 1888. 4d.

To dispense with the usual preliminary mordanting in dyeing cotton with alizarin and analogous dyestuffs, the material is dyed at once in a bath containing the colour stuffs "along with the substances necessary to make them take on to the texture." As example, for dyeing mauve, 100 kilos. of cotton are immersed cold in a bath containing 10 kilos. of the following mixture diluted with 2,500 litres of water: 2 parts of Alizarin No. 1; 1 part of "silicate of soda, 45°"; 2 parts of pyrolignite of iron (specific gravity not stated). The dye-bath is gradually heated to the boiling point in half or three-quarters of an hour. Similarly a rose colour is produced from a mixture of alizarin, acetate of alumina, oil, and a salt of tin; green by substituting ceruleine and bisulphite of soda for the alizarin in the last mixture; and other shades from similar suitable mixtures.

—W. E. K.

*A Process for Dyeing with Yellow, Orange, and Red Azoic Colouring Matters.* J. Imray, London. From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, Paris, France. Eng. Pat. 197, January 4, 1889. 4d.

Two colouring matters described in Eng. Pats. 9315 and 11,976 of 1887 (this Journal, 1888, 499 and 563), were there stated to dye unmordanted cotton in an alkaline bath. This patent relates to a process of dyeing found to give the best results, and is especially applicable to colouring matters derived from phenol, resorcinol, naphthol, and their sulphonic and carboxylic acids. The colouring matters are dissolved in water rendered strongly alkaline by an excess of caustic soda, and sodium chloride is then added up to the point at which the colouring matter is precipitated at a low temperature. In such a bath, when heated, cotton becomes perfectly dyed until the bath is almost exhausted; whereas if the addition of sodium chloride be omitted cotton can only be dyed in presence of great excess of the colouring matters. The sodium chloride may be substituted by other salts having a similar precipitating action. After dyeing (and without rinsing) the cloth is passed through acidulated water, which fixes the colouring matter. An example is given of the method of applying this process in the case of the red colouring matter obtained "by combining the diazoic derivative of an azoxytoluidine with one of the sulpho-naphthols."—W. E. K.

#### VII.—ACIDS, ALKALIS, AND SALTS.

*The Fixation of Atmospheric Nitrogen.* A. A. Breneman. Amer. Chem. Soc. J. 11, 1—45.

**PART I.—Historical Summary showing the Progress and Development of Processes for the Manufacture of Cyanogen and its Derivatives.**—Prussian blue was discovered about 1710 by Diesbach, who happened, in handling a sample of Dippel's animal oil made from blood, to add to it a solution of potash and obtained a blue colour. (Richardson and Watts' Chem. Tech., Vol. 1, p. 1 *et seq.*) Woodward, in 1724 (Phil. Trans. 1724, 33—34, 15—25) deflagrated saltpetre and argols, and fused the product with dried blood; the mass was lixiviated with water and the solution treated with copperas and alum, which gave a green precipitate, becoming Prussian blue when heated with hydrochloric acid. Brown, in the same year (*loc. cit.*) proposed the use of flesh, and Geoffrey in 1725 that of wool and charred horn.

Potassium ferrocyanide was first made by Macquer (1750—1760?) who treated Prussian blue with potash. Beaumé, in 1773, proved the presence of iron in it, and Gay Lussac, in 1814, first showed the existence of cyanogen in Prussian blue and its derivatives. Liebig's investigation led to the theory at present held as to the chemistry of the process, still the only one in use, for making yellow prussiate. From 1820 to 1837 Muspratt, Mackintosh, Gautier (J. de Pharm. 1827, 11), Gentele (Dingl. Polyt. J. 129, 362), and Naumann improved the manufacture; but up to this time (1837) at least two-thirds of the nitrogen had been lost during the fusion, and the first attempt to recover this was made when Kuhlmann, in 1838 (J. prakt. Chem. 26, 410), discovered that cyanogen and ammonium cyanide were formed by passing ammonia over red-hot charcoal, a discovery which Jacquemyn applied to the waste gases from the prussiate pots; the process was patented by Berry (Eng. Pat. January 21, 1840).

*Cyanogen from Atmospheric Nitrogen.*—Zinken, in 1813 (J. prakt. Chem. 25, 246), and Koeb, in 1819, noticed a fused salt in the lower parts of some furnaces; Berthier, in 1826 (Jsb. Chem. Tech. 1879, 28), found potassium carbonate in a similar product, while Dawes, in 1835, announced the existence of potassium cyanide in such deposits. In 1837 Neilson first introduced the hot blast at the Clyde iron furnaces, and an exudation of fused salt

soon afterwards occurred on the walls of the hoshes; Clark showed this to contain 43.4 per cent. of KCN and 45.8 per cent. of  $K_2CO_3$  (Pogg. Ann. 40, 315; Dingl. Polyt. J. 65, 466). This furnace went on producing potassium cyanide for three years. Zinken and Bromels (J. prakt. Chem. 25, 246) and Redtenbacher also noticed the production of potassium cyanide in blast furnaces.

Bunsen and Playfair (Brit. Ass. Report, 1845) drew gases from a blast furnace at Alfreton at a point 2 ft. 9 in. above the tyeres, and found that they consisted of N, 58.65 per cent.; CO, 37.43 per cent.; H, 3.18 per cent.; C<sub>2</sub>N, 1.34 per cent. Potassium cyanide was also condensed from the gases on cooling. Above the hoshes, and as low as the tyeres, no cyanides were found, the conditions for their production being evidently a reducing atmosphere and a high temperature; the latter, Bunsen and Playfair put at not lower than that at which potassium oxide is reduced by carbon. Smith (Chem. News 1865; Jsb. Chem. Tech. 11, 54), and Kirpely (Jsb. Chem. Tech. 1879, 44) also describe fused furnace salts, and the former found one to contain potassium cyanate, 21.45 per cent.; potassium cyanide, 47.73 per cent.; and potassium carbonate, 10.13 per cent.

Lewis Thomson, in 1839 (Dingl. Polyt. J. 73, 281), proved that potassium cyanide is produced when coke, potash, and iron filings are heated together to a bright red in air, and Fownes and Young (J. prakt. Chem. 26, 407), in 1841, confirmed this statement, using carbon from cane sugar and pure potash. In the following year Erdmann and Marchand (J. prakt. Chem. 26, 412) repeated Fownes' experiments, with uncertain results; they asserted that no cyanogen was formed when the materials were dry; and Berzelius (Jsb. d. fortschr. d. Chem. 1844, 23) pointed out that this result confirmed the earlier result of Wöhler, and suggested that the water first formed ammonia, which was then converted into cyanogen. Langlois (Ann. Chim. Phys. [3], 1, 177) proved that cyanogen is formed whether the air be dry or wet.

Bunsen and Playfair (*loc. cit.*) passed nitrogen over a mixture of carbon and potash heated to bright redness, and obtained potassium cyanide. Rieken (Dingl. Polyt. J. 121, 286) found that a white heat was necessary. Diebrich (Jsb. Chem. 1, 473) showed that related reactions also cause combination of C and N:—thus nitric oxide and "potassium carbonic oxide" produced cyanogen when heated together; carbon dioxide, when mixed with ammonia or nitrogen, and passed over hot potassium, or ammonium carbonate kept in contact with fused potassium, yielded cyanogen.

A. V. Newton first patented a process for obtaining cyanides by passing N from any source, but free from "oxidating substances," through a layer of small pieces of charcoal saturated with potashes and heated to redness, the vapours containing cyanides to be absorbed by suitable liquids (Dingl. Polyt. J. 95, 293; Eng. Pat. 9985, December 13, 1843). He recommends the use of the waste gases from sulphuric acid chambers after passing through ferrous sulphate and lime water, to absorb oxides of nitrogen. The best proportion of potash to charcoal is from 25:100 to 100:100, according to the density of the latter; the nitrogen should always be in excess, and is best under pressure, much friction with the charcoal being advantageous.

Possoz and Boissiere (Jsb. Chem. Tech. 1855, 83; 1858, 191; Dingl. Polyt. J. 104, 446; 107, 444; 129, 361; 149, 56), before the date of Newton's patent, had a factory at Grenelle, Paris, which turned out 15,000 kilos. of yellow prussiate per annum manufactured on this principle. In 1844 they removed to Newcastle-on-Tyne, where they received the co-operation of Bramwell and Hughes, and in 1845 the output was more than a ton per day. These works were closed in 1847, after considerable loss. The cost of production was said to be less than 2 francs per kilo., and the salt of fine quality. In their latest form the retorts for this process were cylinders of firebrick 10 ft. long and 2 ft. in diameter, with walls 9 in. thick; lateral slits in the walls served for admission of air and stirring of the contents. The alkalis charcoal, which contained 30 per cent. of potash, was prepared by saturating the charcoal with potash solution, and was fed into the top of the cylinder, being thus dried by waste heat. The cylinders were kept at a white

heat and the gases pumped through them. The cyanised charcoal was withdrawn at the bottom and thrown into water containing spathic iron ore. The production of cyanide for a given weight of potash was said to be greater than in the ordinary prussiate process; soda was inferior to potash, and even small quantities of water hindered the production of cyanides. Failure was due to cost of retorts and volatilisation and other loss of alkali.

The patents of R. Laming, Swindell, and J. Laming (Eng. Pats. 9832, July 13, 1843; June 12, 1844; 10,955, November 18, 1845) describe methods similar to the above, but using other sources of nitrogen. Bunsen (Brit. Ass. Rep. 1845) proposed a furnace on the plan of the blast furnace, fed with alternate layers of alkali and charcoal.

Armengand (Dingl. Polyt. J. 120, 111; Genie Industriel, 1853, 315) and Eitel (Dingl. Polyt. J. 120, 77; French Pat. November 16, 1846) patented processes which differed from that of Possoz and Boissiere in the use of steam and a comparatively low temperature.

Marguerite and Sourdeval (Jsb. Chem. Tech. 1873, 361; Ber. 6, 79), in 1862, found that a hot mixture of baryta and carbon absorbed N from the air, forming barium cyanide, which yields ammonia in presence of steam at 300°. Messrs. Brin, in 1883 (Eng. Pat. 5802, December 18, 1883; also this Journal, 1884, 173), patented a process for making ammonia by passing N over heated coke containing baryta.

In 1868 Berthelot discovered the synthesis of HCN from  $C_2H_2$  and N; he concluded that potassium acetylene,  $C_2K_2$ , is first formed in the above cyanide processes, and that this then combines directly with N.

In 1878, Blair (Scientific American, 1878, 21; Dingl. Polyt. J. 230, 93) patented an apparatus, and in 1879 Weldon (Jsb. Chem. Tech. 1879, 472) a rotary furnace for the manufacture of cyanides by the charcoal-potash-nitrogen method. The latter found a bright red heat sufficient.

Alder, in 1881 (J. Chem. Tech. 1881; D.R. Pat. 1881, 12,351, and 1882, 509) claimed that the presence of finely-divided iron is beneficial, and used lime together with sulphides and sulphates of the alkali metals instead of potash.

Ludwig Mond (U.S. Pat. 269,309, December 19, 1882; compare this Journal, 1889, 506) in 1882 patented a process similar to that of Marguerite and Sourdeval (see above. Compare also Readman, this Journal, 1889, 758).

Fogarty, in 1883 (U.S. Pats. 288,323 and 402,324, November 13, 1883), dropped a mixture of powdered carbon and alkali into superheated furnace or generator gases, whereby cyanides were produced and subsequently decomposed by the steam present, yielding ammonia. This process has been tried on a large scale without commercial success.

Young, in 1884 (Eng. Pat. 16,046, December 6, 1884; also this Journal, 1886, 34), patented the use of magnesium limestone for constructing furnaces for cyanide processes.

Siepermann (Jsb. Chem. Tech. 1887, 675) obtained cyanates by passing ammonia over a mixture of barium carbonate with alkaline carbonate, adding coal if cyanides are wanted. He finds a moderate red heat best. Dickson (U.S. Pat. 370,768, October 4, 1887) injects a mixture of air, steam, coal-dust, and powdered alkali into a chamber heated by the combustion of the injected fuel, thus producing cyanides and ammonia.

**Formation of Metallic Nitrides.**—Wagner (Jsb. Chem. Tech. 1857, 121) suggested the nitrides of boron and silicon in the interior of the earth as the source of volcanic ammonia; but Bunsen and Rainer regard this ammonia as of organic origin.

Briegleb and Geuther, in 1862 (J. prakt. Chem. 123, 228), investigated metallic nitrides, obtaining those of magnesium, aluminium, and chromium by heating the metals in pure N. Magnesium nitride yields cyanogen when heated in CO or CO<sub>2</sub>. Tessie de Motay (Jsb. Chem. Tech. 1873, 279; Ber. 5, 395) found that titanium nitride yields ammonia when heated in steam, and can be regenerated by being heated in N.

**Cyanides from Oxides of Nitrogen.**—Blinks (J. prakt. Chem. 101, 359; 103, 230; 105, 69; 110, 248) passed hydrocarbon vapours mixed with nitric acid vapour or oxides of nitrogen over highly-heated firebrick. With hydro-

carbons in excess, cyanides are the chief products; with nitrogen compounds in excess, ammonia is mainly produced. Firman proposed to use gases from sulphuric acid chambers.

Roussin, in 1858 (*Compt. Rend.* **67**, 875; *J. prakt. Chem.* **78**, 375), suggested the deflagration of sodium nitrate and acetate as a source of cyanide.

*Production of Cyanides from Ammonia.*—Clouet, in 1791 (*Ann. Chim. Phys.* **11**, 30; *J. prakt. Chem.* **26**, 408; *Crell's Annalen*, 1796), mentioned that ammonia passed over hot charcoal yields hydrocyanic acid. Tromsdorff (*J. prakt. Chem.* **26**, 409) showed that the product was ammonium cyanide. Kuhlmann (*loc. cit.*; *Liebig's Annalen*, **38**, 62; *J. prakt. Chem.* **16**, 482) found that nitrogen compounds mixed with hydrogen or hydrocarbon vapours yield ammonia when passed, together with carbonic oxide, over red-hot platinum sponge.

Graeger (*Jsb. Chem. Tech.* 1858, 184) passed vapour of ammonium carbonate over alkaline charcoal in iron cylinders, 1½ in. diameter, and obtained 93–95 per cent. of the theoretical yield of ferrocyanide. The narrow cylinders were necessary. Brunquill, in 1856 (*Preuss. Verhandlungen*, 1856, 30; *Jsb. Chem. Tech.* 1856, 102; *Dingl. Polyt. J.* **140**, 374, 452), applied this principle by passing ammonia, or the vapours from distillation of bones, over hot firebrick and then over hot wood charcoal in pieces of the size of a chestnut. The ammonium cyanide was absorbed by solution of ferrous sulphate and the cyanides of iron converted by potash or soda into prussiates. Only moderate temperatures were employed.

Levoir, in 1859 (*J. prakt. Chem.* **76**, 447; *Dingl. Polyt. J.* **153**, 466), noticed that a flame of ammoniacal gas yielded cyanogen (ammonium cyanide), a statement questioned by Fischer (*Dingl. Polyt. J.* **157**, 466), and verified by Romily in 1867, who passed illuminating gas through ammonia and burned it, causing the flame to impinge on a surface of water containing potash (*Compt. Rend.* **64**, 320; **65**, 865; *Jsb. Chem. Tech.* 1867, 761); potassium cyanide was found in solution if the flame was smoky or luminous. The process was tried commercially.

Johnson (*Dingl. Polyt. J.* **156**, 212; *Jsb. Chem. Tech.* 1860, 221) and Webster (*Eng. Pat.* 1913, August 8, 1860) patented processes for making prussiate by passing ammonia over alkali charcoal.

Fleck, in 1863 (*Polyt. Centrbl.* 1863, 717; *Dingl. Polyt. J.* **169**, 209; *Jsb. Chem. Tech.* 1863, 323), proposed treating a hot mixture of charcoal or coal, sulphur, and potash with a definite quantity of ammonium sulphate; potassium sulphocyanate is formed and converted into potassium cyanide by metallic iron; 94.42 per cent. of the ammonium salts are claimed to be ultimately obtained as cyanides. Meyer, in 1874, asserted that the process was not practically successful.

Gelis (*Jsb. Chem. Tech.* 1862, 283) made prussiates by mixing cold solutions of ammonium sulphhydrate with carbon disulphide; the ammonium sulphocarbonate formed was converted by potassium sulphide into the potassium sulphocyanate, which yields prussiate when treated with iron. The cost was said by Payen to be 1.6 francs per kilo. of potassium ferrocyanide; but the process was condemned as wasteful by Meyer, and abandoned.

Schwarz (*Bull. Soc. Chim.* 1869, 167; *Dingl. Polyt. J.* **191**, 399; *Jsb. Chem. Tech.* 1869, 269) obtained ammonium cyanide by passing vapour of carbon disulphide mixed with ammonia over hot iron, or copper, in an iron tube. The cyanide was converted into Prussian blue and then into prussiate.

E. Meyer, in his review of the cyanogen industry up to 1873 (*Jsb. Chem. Tech.* 1874, 442), found that no method proposed up till that time had succeeded as well as that of Possoz and Boissiere, which, however, had failed to replace the original fusion method.

Maxwell-Lyte (*U.S. Pat.* 161,137, March 23, 1875) patented a process for making ammonia by bringing nitrogen in contact with nascent hydrogen, liberated in presence of a triad or pentad element.

Tscherniak and Gunsberg patented, in 1878 (*D.R. Pat.* 3199, April 9, 1878; *Ber.* **12**, 140; *Dingl. Polyt. J.* **232**, 80; *Jsb. Chem. Tech.* 1879, 471; 1882, 570), a method for making cyanides, similar to that of Schwarz.

Graham Young (1880) suggested the use of electricity for combining nitrogen and hydrogen.

*Decomposition of Alkaline Hydrates by Metals in Presence of Air to produce Ammonia.*—Dufréné, in 1880 (*Eng. Pat.* 5478, December 29, 1880), patented a process for making ammonia by combustion of zinc in air in presence of an alkaline hydrate; hydrogen and nitrogen are both set free and combine as ammonia in presence of hot iron, or platinum sponge. Twineh (*Eng. Pat.* 3712, August 25, 1881) removes oxygen from the air by nitric oxide, and brings the nitrogen in contact with nascent hydrogen from the decomposition of steam, or of alkaline hydrate, by metals, to produce ammonia.

**PART II.—An Inquiry in Regard to the Conditions under which Cyanogen is produced by Direct Union of Nitrogen and Carbon.**—The condition of free nitrogen is that of two atoms joined to one another to form a molecule and requiring the expenditure of a certain quantity of heat to tear them apart and leave each atom free to enter into new combination.

The most prominent source, and perhaps the only true source, of nitrogenous compounds in nature is found in the union of nitrogen and oxygen of the air under the influence of electric discharge.

Nitrogenous compounds have heretofore only been obtainable from substances already containing nitrogen, and the discovery that the conditions of the blast furnace are at times those necessary for the fixation of atmospheric nitrogen by combining it with carbon, gave rise to the hope that the problem as to how atmospheric nitrogen could be directly pressed into service as a source of nitrogenous compounds was at last solved. Such has not however proved to be the case, notwithstanding the many experiments that have been tried, which have been summarised in Part I. of this treatise. We have now to inquire what are the essential and what the non-essential conditions for the fixation of free nitrogen as cyanogen? The study of the blast furnace shows that a high temperature, a reducing atmosphere, an alkaline flux, and an excess of nitrogen are conditions favourable to the process of fixation, but as yet the conditions most suitable for the process remain undefined.

The author proceeds to discuss, by the light of the experiments summarised in Part I., the influence which temperature, the presence of oxygen and of water, the time of contact between the nitrogen and carbon, the degree of subdivision of the carbon, and the alkalis or other bases, has upon the formation of cyanogen from carbon and nitrogen; also the nature of the base to be employed in the process; the relation which ammonia bears to cyanogen and the conditions which determine the formation of the one or the other; the influence of other gases upon the absorption of nitrogen by carbon; the influence of hydrocarbons in the preparation of cyanogen or ammonia; finally, the influence of pressure upon the process. The results of the discussion are fully summarised as follows:—

**SUMMARY** of the present aspect of the question:—

The manufacture of cyanides and ammonia from the nitrogen of the air, while quite possible on the small scale, is beset with difficulties in its economical and commercial application, which, up to this time, have been insurmountable. These difficulties are probably matters relating mainly to construction and the endurance of materials.

At the same time there is still much uncertainty in regard to the chemical and physical conditions most favourable to the fixation of nitrogen.

The following conclusions are the results of the forgoing inquiry:—

1. The temperature necessary for formation of cyanogen may be lower than at first supposed, but certainly not below a high red heat. For ammonia a low red heat is sufficient.
2. The presence of free oxygen is deleterious in all cases.
3. Water in very small quantities is not prejudicial to production of cyanogen, and an excess is probably necessary in the synthesis of ammonia.
4. The long-continued contact of carbon and nitrogen is of less importance than thorough commingling of all reacting materials.
5. The presence of a strong base is essential, but under certain conditions ammonia, produced synthetically, may

serve the purpose of a base and effect the synthesis of ammonium cyanide.

6. Alkaline bases are preferable, potash especially, and probably because of the intermediate action of metallic potassium, which is reduced at a lower temperature than sodium. Baryta is the best of the alkaline earths for the purpose.

7. Ammonia and cyanogen are probably formed under conditions differing in respect to temperature and moisture, but otherwise similar, as already indicated.

8. The presence of carbonic oxide and of reducing gases in general, is probably favourable, while oxygen, carbonic acid and steam in excess (the latter only in the case of cyanogen) are probably injurious. Nothing is known as to the influence of sulphurous acid or hydrogen sulphide, but they are probably undesirable.

9. The presence of hydrocarbon vapour is favourable, and may, under certain conditions, permit the formation of both cyanogen and ammonia without the presence of a base.

10. There are no direct data for estimating the influence of pressure upon the reaction in question. The application of pressure is at least worthy of trial.

In the discussion which followed this paper, Dr. Waller referred to the formation of calcium chromate by heating chrome iron ore with lime, as an example of the formation of a salt aided by the presence of a base. Dr. Alberg remarked that the addition of lime would in some cases contribute only physical conditions which would aid in the reaction, such as porosity and infusibility; he added, as his opinion, that even the momentary formation of some compounds does not take place unless a base is present to fix them as soon as formed. [Professor Breneman in his paper having expressed his opinion that the base has no predisposing effect in inducing the formation of cyanogen, only serving to remove it from the sphere of action as soon as formed.] Dr. Doremus referred to the action of  $MnO_2$  on  $KClO_3$ . Mr. Sabin said the escape of nitrogen as ammonia in the old prussiate process was often very great; he doubted if any cyanide manufacturers in this country, with the exception of a firm at Newark, who are using an improved pear-shaped retort heated only at the central wide portion, are making it pay. Dr. Alberg referred to the increased manufacture of cyanides and ferrocyanides in Germany from gas purifier waste; at present the only practical process for making cyanides from sulphocyanides is by heating the latter with finely divided iron under pressure at  $120^{\circ}$ – $140^{\circ}$  C., whereby ferrocyanide and ferrous sulphide are formed. Dr. Doremus said that the Wilkinson process for manufacturing wood gas produced little cyanogen and no ammonia. Professor Breneman thought that the amount of ammonia and cyanide produced in gas retorts is possibly larger than that due to the nitrogen of the coal alone, though the access of atmospheric nitrogen cannot be very free.—A. G. B.

#### On Ammonia-Soda Processes. II. Schreib. Zeit. f. angew. Chem. 1889, 445–448 and 486–489.

IN a previous communication (this Journal, 1888, 434) the author indicated the line of work which he has followed up in the present article, and upon which he has founded a patented process for treating the mother-liquor of the sodium bicarbonate so as to fit it for use again in the carbonating towers. The process is based upon three reactions: (1) sodium chloride will precipitate ammonium chloride from concentrated solutions until the two salts are contained in the solution in equivalent proportions; (2) the solution so constituted will take up a large quantity of ammonium carbonate, whilst a further quantity of ammonium chloride becomes precipitated; (3) a low temperature will cause a further quantity of ammonium chloride to separate out and the resulting solution will dissolve sodium chloride. The three reactions are used simultaneously in actual work, but in order to ascertain their respective influences the author has examined them singly. By treating a saturated solution of ammonium chloride with solid sodium chloride and continual agitation, ammonium chloride separates out in flakes. Although the resulting solution contained the two

salts in approximately equivalent proportions, the relation was never quite constant. The results of several experiments averaged:—

Specific gravity.....	1.1758
Grms. per 100 cc.	
Total salts.....	37.17
NaCl.....	20.05
$NH_4Cl$ .....	17.12
Temperature of experiment.....	$20^{\circ}$

A similar but more imperfect result is given by the inverse reaction, in which a saturated solution of sodium chloride is agitated with solid ammonium chloride. The results of several experiments averaged:—

Specific gravity.....	1.18195
Grms. per 100 cc.	
Total salts.....	35.63
NaCl.....	23.71
$NH_4Cl$ .....	11.92

By evaporating a solution containing the two salts in exactly equivalent proportions, the salts crystallised out in the same proportions and the boiling mother-liquor contained the salts in the same relative quantities, but on cooling this mother-liquor to  $2^{\circ}$  and  $-5^{\circ}$ , only ammonium chloride crystallised out. On passing ammonia gas into a solution of the two salts, both chlorides separate out, but on passing a current of carbonic just sufficient to form normal ammonium carbonate, only ammonium chloride separates out.

The effect of these successive reactions on a pure ammonium chloride solution is shown in a tabular form:—

	$NH_4Cl$	NaCl	$NH_3$	$(NH_4)_2CO_3$
	Per Cent.	Per Cent.	Per Cent.	Per Cent.
I. Solution of $NH_4Cl$ .....	28.72	..	..	..
II. On treatment with NaCl at $20^{\circ}$ .....	17.12	20.05	..	..
III. On treatment with $NH_3$ gas .....	15.93	16.75	6.71	..
IV. On treatment with $CO_2$ gas .....	13.04	17.78	..	18.80
V. On cooling to $-5^{\circ}$ and shaking with NaCl .....	8.05	23.40	..	18.80
VI. After treatment of solution II. with $NH_3$ , $CO_2$ , and NaCl at $45^{\circ}$ , and subsequent cooling to $2^{\circ}$ and shaking with NaCl .....	4.10	25.50	..	19.50

On treating solution VI. with  $CO_2$  gas to saturation, sodium bicarbonate was precipitated, leaving a solution containing—

	Per Cent.
$NH_4Cl$ .....	21.0
NaCl.....	9.0

It is not advantageous to use commercial ammonium carbonate for these experiments, owing to the presence of the acid salt, which would precipitate sodium bicarbonate along with the desired ammonium chloride.  $NH_3$  and  $CO_2$  are best obtained in the right proportions by distilling a mixture of calcium carbonate with sal-ammoniac.

In order to adapt the process to the ammonia-soda manufacture, the apparatus shown in Fig. 1 is employed. The liquor leaving the sodium bicarbonate filters which contains the mixed chlorides of sodium and ammonium is pumped into the vessel A, which is connected with B by pipes *a* and *b*. B is filled with lumps of sodium chloride which rest on the perforated plate *c*. When the two vessels are filled with liquor to the level *i*, the salt in B becomes dissolved, and the liquor, by reason of its increased density, flows downward through *b* into A, whilst fresh liquor flows in through *a*. At the same time ammonia and carbonic acid are passed in through *d*, care being taken to have always an excess of ammonia present. The rise of temperature caused by the reaction should be allowed to reach  $50^{\circ}$ , in order to dissolve the maximum quantity of salt. *g* is a pipe for

applying air pressure to B to drive out its contained liquor when it requires refilling with salt. When the liquor in A has been sufficiently charged with ammonium carbonate, it is cooled by the passage of cold water through the coil K. The temperature should be lowered to  $5^{\circ}$  if convenient, and

Fig. 1.

in any case to  $10^{\circ}$ . When sufficiently cold water is not available, artificial cooling must be resorted to. When the liquor is cool enough, it is allowed to settle and the clear liquor is drawn off, the rest being separated from the precipitate by filtration and compression. Sal-ammoniac as thus obtained consisted of 98 per cent.  $\text{NH}_4\text{Cl}$  and 2 per cent.  $\text{NaCl}$ . The clear liquor is sent into the carbonating towers. Fig. 2 shows the arrangement of plant in an

A = Lime kiln.

ammonia-soda factory in which the recovered ammonium chloride is decomposed in the dry way by heating it with powdered chalk in retorts. C are carbonating towers in which the ammoniacal salt solution is saturated with carbonic acid; these towers have vessels for holding salt like the apparatus shown in Fig. 1. The contents of the towers are brought upon the filters F, which retain the sodium bicarbonate and allow the liquor to flow into the montejes M, from which it is pumped into the regenerators R, described under Fig. 1. Here the liquor receives ammonium carbonate evolved from the retorts O, and is subjected to the special treatment under notice. The finished charge is sent into the filters G, from which the liquor goes to the montejes N,

to be pumped into the carbonating towers again. The sal-ammoniac left on the filters is sent into the presses P for the more complete removal of adhering mother-liquor. The recovered sal-ammoniac may be worked up in the wet way by distillation with milk of lime, with the advantage of making the liquors of any desired strength, and of obtaining finally a solution of calcium chloride nearly free from sodium salt. It might also be possible to decompose the strong solution of ammonium chloride by some form of calcium carbonate (compare this Journal, ). But the simplest method of treating the recovered ammonium chloride is to mix it with powdered chalk and to heat the mixture in retorts, by which ammonia and carbonic acid are obtained together, and a residue of solid calcium chloride is left in a condition which may be especially suitable to a process for obtaining chlorine. The author refers to the loss of sodium bicarbonate arising from the use of water for washing out the mother-liquor from the mass on the filters, and thinks that mineral oil might be used for expelling the mother-liquor and avoiding loss of product.—G. H. B.

*The Electrolysis of Sodium Chloride Solution with Direct Production of Chlorine and Crystallised Soda.*  
W. Hempel. Ber. 22, 2475—2478.

THE author is studying with J. Fogh the electrolysis of chlorides under such conditions that the ions are prevented from entering into secondary reaction. The simplest method of securing this complete separation of the ions is by conversion into relatively insoluble compounds. In the case of sodium chloride, advantage is taken of the insolubility of sodium carbonate and bicarbonate in the saturated solution of sodium chloride, i.e., the sodium hydrate is converted into these compounds by the action of carbonic acid at the cathode. The apparatus employed by the author is shown in section in the annexed drawings. The electrodes are circular (Fig. 1). For the cathode iron plate is used; for

Fig. 1.

the anode, retort carbon. They are perforated at numerous points, as shown (Fig. 2), the perforations being so made as to permit the escape of gas bubbles upwards. Between the electrodes a fine sheet of asbestos paper is secured, the distance between the electrodes being about 1 mm. At a, a, chambers are constructed on either side of the electrodes by means of porcelain rings, that in the cathode chamber being perforated to allow the entrance of the tube conveying the carbonic acid, also the withdrawal of the sodium carbonate produced and there collected. The only detail of construction especially noteworthy is the insertion of the asbestos between the electrodes. This the

author contrasts with and finds superior to the arrangement patented by J. Marx (D.R. Pat. 46,318), who claims to secure the isolation of the products of electrolysis by means

Fig. 2.

of diaphragms of gauze. He also notes that his investigation was commenced at a period prior to the publication of the specification of the patent in question, which claims the conduct of the electrolysis under conditions otherwise similar in every respect. The results obtained by the author are as follows:—

The E.M.F. required is made up of 3.2 volts for the decomposition of the chloride, plus 2.5 volts for the back E.M.F. With a current of 1.73 amperes at this voltage the yield of chlorine amounted to 0.930 grm. per hour. Taking the equivalent of 1 h.p. at 680 volt-amperes, the total production would be 64.5 grms. of chlorine and 259.8 grms. of  $\text{Na}_2\text{CO}_3 \cdot 10 \text{H}_2\text{O}$  per horse-power per hour. (See also Eng. Pats. 13,306, 14,199, and 14,239 of 1888; this Journal, 1889, 778.)—C. F. C.

*The Distribution of the Liquid in Gay-Lussac-, Glover-, and Hydrochloric Acid Towers, &c.* G. Lunge. Zeits. f. angew. Chem. 1889, 603—605.

THE author remarks that he has found the old method of distributing the liquid in coke towers by means of "reaction distributors" entirely replaced by an overflow arrangement in many of the works in London, Lancashire, on the Tyne, and in the North of France. The following figures show the method adopted, Fig. 1 being a plan, Fig. 2 a through section, and Fig. 3 a general view of the apparatus, which

Fig. 1.

Fig. 2.

Fig. 3.

is generally made of lead. The liquid to be distributed enters through the cock *a*; where a mixture of two liquids is fed into the tower (e.g., in the Glover tower) two cocks are attached to the pipe. The pipe conveying the liquid is fixed into the circular trough *A*, provided with a cover *b*. Holes are cut in the base of *A*, through which the liquid has free access to the shallower trough *B*. *C* is a wider trough of the same depth as *B*, and is divided up into a number of compartments *e* (16 in this case), each of which is separately connected with *B* by the small spouts *c* shown in the figure. Each partition *e* has a pipe *d*, sealed by means of a hydraulic float, attached to it, and through these

Fig. 4.

the liquid passes down the tower. The spouts in the divisions *e* are best so arranged that, should a stoppage occur in any one of them, the excess of liquid runs over into the adjacent compartments, and not outside the trough C. In order to regulate and to control the supply of liquid, a leaden vessel, shown in Fig. 4, is used in many works, and is placed between the supply pipe and the trough A. The two compartments D and E communicate by means of the tubes *f, g, h, i*, and the spout *k*, so that the workman has only to be told how many of the pipes he is to have working to ensure the passing of the right quantity of liquid.—C. A. K.

*Adulteration of Chili Saltpetre with Stassfurt Potassium Salts.* O. Böttcher. *Sächs. landw. Zeitschrift*. 1889, **37**, 192–193.

Two samples of Chili saltpetre showed by their high percentage of potash, chlorine, sulphuric acid, and magnesia, coupled with a low percentage, 8.57–8.71, of nitrogen, that they consisted of about half of potash salts, and could not be regarded as saltpetre. Unadulterated Chili saltpetre is composed about as follows:—nitrogen, 15.5 per cent.; chlorine, 1.7; sulphuric acid, 0.7; soda, 35.0; water, 2.6; sand, 1.5, &c.—D. A. L.

*The Life of Sulphuric Acid Chambers.* A. Burgemeister. *Chem. Zeit.* **13**, 1633–1634.

In order to gauge the rate at which the walls of sulphuric acid chambers are corroded by the action of the chamber gases and acid, a number of measurements were made of the thickness of the walls of two chambers, built respectively in 1865 and 1876.

The chamber built in 1865 is a No. 2 chamber, and during the 285 months between December 1865 and end of September 1889, was working for 210 months, and idle for the remaining 75 months. Its capacity is 1,559 cubic metres, and it was originally constructed of lead 2.57 mm. thick. The average of many measurements showed that the thickness in October 1889 was 1.88 mm., a decrease of 0.69 mm. This is equal to a loss of 7.86 kilos. per square metre, or 26.8 per cent.

The other chamber belongs to the same set as the last-mentioned one, and has been used as No. 1 chamber in that set. It has a capacity of 257 cubic metres. It was rebuilt in 1876, of lead 3.40 mm. thick. Owing to its position in the set it has been worked at a higher temperature than the No. 2 chamber (at from 65° to 90° C.). It has been at work 120½ months in all. Measurements taken in October last showed the average thickness of its walls to be 2.80 mm., a reduction of 0.60 mm., equal to a loss of 6.84 kilos. per square metre, or 17.65 per cent.

The action on the walls of these chambers was of course not uniform. Those parts of the walls in contact with the acid lying in the chambers were found to be most acted upon, and in some parts of this region the lead was as thin as paper, whilst in places, during many years past, holes have been eaten through. Next, those parts were most acted upon where the lead overlapped and where the wooden framework prevented its cooling. When the seams are burnt from the inside, an overlapping strip is left outside, and in such places the inner thickness of lead is soon eaten through, and the seams leak. When, on the contrary, the seams are burnt from the outside, they do not leak until the outer sheet of lead is also eaten through. The floor is the part of the chamber least acted upon, as the acid covering it at the relatively low temperature of 40°–60° C. does not corrode the lead so vigorously as do the warmer gaseous contents of the chamber.

Lunge (*Sulphuric Acid and Alkali*, Vol. I. 281) says: "Under normal circumstances a chamber will generally last from eight to 10 years, but with many repairs during the latter years." The above instance shows that a much greater age may be reached.—H. S. P.

## PATENTS.

*Improvements in the Manufacture of Cyanogen Compounds from Sulpho-cyanides.* T. Parker and A. E. Robinson, Wolverhampton. Eng. Pat. 17,447, November 30, 1888. 4d.

A SOLUTION containing about 20 per cent. of the sulpho-cyanide and acidified with sulphuric acid is subjected to the action of an electric current at a density of from 10 to 30 ampères per square foot of anode. The resulting gaseous hydrocyanic acid may be led off and condensed in water, leaving a sulphate in the original solution.—B. T.

*Improvements in Salt-cake Pots.* D. Y. Cliff, C. Cliff, P. Cliff, and B. Cliff, Leeds. Eng. Pat. 17,459, November 30, 1888. 4d.

THE improvements consist in making "salt-cake pots" from fire-clay and other clay or cement.—F. S.

*Improvements in Flat or Prismatic Evaporating Pans for the Treatment of Salt.* M. and H. Fläsehdreger, Arnshall, Germany. Eng. Pat. 17,541, December 1, 1888. 6d.

THE evaporating pan is provided with a heating boiler which extends nearly the whole length of the pan, and is provided with vertical sides with water or flue tubes. The boiler is furnished with a lid, having "bent-over bevelled edges" so as to prevent the grains of salt solution in the pan and those settling at the bottom from entering the boiler. By this arrangement a better evaporation, as well as a rational consumption of the fuel, is claimed.—F. S.

*Improvements in Evaporating Brine and other Solutions.* Sir Lowthian Bell, Northallerton. Eng. Pat. 17,564, December 1, 1888. 6d.

THE invention consists in utilising the waste heat of slag derived from iron furnaces and furnaces employed in other metallurgical operations. The slag may be received into iron vessels mounted on wheels and capable of containing several tons. These vessels when charged are caused to be passed down an incline into a chamber, over which an evaporating pan of large area is set. When the slag blocks are in the chamber they are sprinkled with water to harden the exterior. Steam is thereby generated, and this steam coming in contact with the bottom of the pan imparts its heat thereto, and so heats the brine or solution which the pan contains. Or the steam thus generated may be passed through pipes immersed in the solution. In the lower part of the chamber also there is water which the blocks of slag, as they progress slowly down the incline, and when they are sufficiently hardened, ultimately reach, and so the water in the chamber is kept at a boiling heat. When the blocks are cooled down to the temperature of the water the carriages on which the vessels containing them are mounted, are passed on up another incline, and so out of the chamber.

In place of using water a current of air may be caused to pass through the chamber in the reverse direction to that in which the blocks travel through it, and the air thus heated may be made to pass beneath the pans containing the brine or solution to be evaporated, the air being led back again to the exit end.—F. S.

*Improvements in or relating to the Treatment of Salt, and in the Means employed therefor.* J. W. Hewson, Stockton-on-Tees. Eng. Pat. 17,807, December 6, 1888. 8d.

AN improvement in the manufacture of blocks of salt, enabling this to be done without regard to when and where the process of evaporating the brine has been carried out, or—what amounts to the same thing—to the amount of heat and moisture contained in the salt at the commencement of this process (except that the proportion of water should not be below that which salt in the free state naturally retains).

The salt is pressed into asbestos-lined iron or tin moulds, and heated in a suitable oven to about 170° F., for about

half an hour. It is then removed from the moulds and heated to about 220° F. for from one to two days.

By this means salt may be shipped in bulk and subsequently converted into blocks, from the state in which it is delivered.

A further important result claimed is the facility afforded for reducing coarse grained to fine table salt, by substituting a cheaper and more convenient grinding process for the boiling process now in use.—F. S.

*A New and Improved Method of Manufacturing Glazing, Antiseptic, and Washing Compounds.* J. Ascough, Handsworth. Eng. Pat. 1430, January 26, 1889. 6d.

THIS improved method consists in manufacturing these compounds by friction, heat, fusing, or fluxing the equivalent or approximate component parts of such compounds together until they become intimately mixed and combined.

It "is primarily associated with boron and sodium compounds, but can be applied to the manufacture of many other chemicals." Thus to make borax, boric acid and sodium carbonate are "frictionized" by grinding or other means, or fused together. The product may be used for purposes for which borax is now used.—F. S.

ERRATUM.

In the November issue for 1889 of this Journal, page 882, col. 2, the formula of the Acid Bisulphite of sodium and potassium should be  $2 \text{Na}_2\text{O}$ ,  $\text{K}_2\text{O}$ ,  $4 \text{SO}_2$ ,  $9 \text{H}_2\text{O}$ , and that of the Acid Bisulphite of sodium and ammonium—

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

*Leadless Glazes.* Seger. Thonind. Zeit. 1889, 13, 524.

THE author has already proposed and practised the substitution of barium glazes containing boric acid for the lead glazes common on stoneware, and has now turned his attention to the production of glazes free from lead capable of receiving the rich and varied colours needed for artistic purposes. He has confined his work to glazes melting at temperatures below the fusing point of gold, that being the limit usually adopted, and starting with a normal calcium glass of the formula  $0.5 \text{K}_2\text{O}$ ,  $0.5 \text{CaO}$ ,  $2.5-3.0 \text{SiO}_2$ , has investigated the effects produced by the addition of alumina, silica and boric acid in various proportions, with the following results: Glazes of the composition  $0.6 \text{K}_2\text{O}$ ,  $0.4 \text{CaO}$ ,  $2.5 \text{SiO}_2$ ,  $0.5 \text{B}_2\text{O}_3$ , with and without the partial or complete substitution of  $\text{Na}_2\text{O}$  for  $\text{K}_2\text{O}$ , fuse below the melting point of silver, and are clear at a little above that of gold; those of the composition  $0.6 \text{K}_2\text{O}$ ,  $0.4 \text{CaO}$ ,  $0.1-0.3 \text{Al}_2\text{O}_3$ ,  $2.5 \text{SiO}_2$ ,  $0.5 \text{B}_2\text{O}_3$ , tend to become opaque as the proportion of alumina increases unless rapidly cooled; on the other hand those poor in alumina have the greater tendency to "crackle." On raising the proportion of silica to  $3.5 \text{SiO}_2$  in the case of the glaze containing  $0.2 \text{Al}_2\text{O}_3$ , the "crackling" was inevitable, and simultaneous increase in the quantity of the boric acid gave a glaze which became opaque on slow cooling; notwithstanding this a glaze of the formula  $0.6 \text{K}_2\text{O}$ ,  $0.4 \text{CaO}$ ,  $0.8 \text{Al}_2\text{O}_3$ ,  $5 \text{SiO}_2$ ,  $1 \text{B}_2\text{O}_3$  proved of general utility.

Glazes containing  $0.5 \text{K}_2\text{O}$  and  $0.5 \text{CaO}$  behaved similarly, and proved useless when the contents of alumina was low. On increasing the quantity of alumina transparent glazes were obtained, the reverse being true of boric acid; thus the glaze  $0.3 \text{K}_2\text{O}$ ,  $0.7 \text{CaO}$ ,  $0.5 \text{Al}_2\text{O}_3$ ,  $4 \text{SiO}_2$ ,  $0.5 \text{B}_2\text{O}_3$  was clear, while  $0.3 \text{K}_2\text{O}$ ,  $0.7 \text{CaO}$ ,  $0.5 \text{Al}_2\text{O}_3$ ,  $4 \text{SiO}_2$ ,  $1 \text{B}_2\text{O}_3$  was opalescent, and  $0.3 \text{K}_2\text{O}$ ,  $0.7 \text{CaO}$ ,  $0.5 \text{Al}_2\text{O}_3$ ,  $4 \text{SiO}_2$ ,  $2 \text{B}_2\text{O}_3$  was like milk-glass; increase in the proportion of alumina, though giving clear glazes, raised their melting points. With regard to the bases in the glazes, the limit  $0.2 \text{K}_2\text{O}$ ,  $0.8 \text{CaO}$  must not be passed, as more lime causes opalescence in all cases.—B. B.

*On Copper-Red.* Lauth and Dutailly. Mon. Céram. et Verr. 19, 237.

NUMEROUS experimenters have endeavoured to arrive at the true Chinese copper glaze, a sample of which, analysed by Ebelman and Salvétat in 1832, had the composition:  $\text{SiO}_2$  73.9,  $\text{Al}_2\text{O}_3$  6.0,  $\text{Fe}_2\text{O}_3$  2.1,  $\text{CaO}$  7.3,  $\text{CuO}$  4.6,  $\text{K}_2\text{O}$  3.0,  $\text{Na}_2\text{O}$  3.1, parts per cent. The authors find that the most successful imitations have a composition of which the main constituents vary within the following limits:—

	Per Cent.		Per Cent.
Alumina.....	10.56	to	5.4
Silica.....	66.00	to	46.5
Alkalis.....	6.29	to	28.0

They lay down the following rules:

(1) The glaze must not be too aluminous. (2) Alkalis rather than lime should be used as basic material. (3) Borax prevents the "crackling" which is apt to be produced by the alumina and alkalis present, and favours the formation of the red colour. (4) Stannic oxide in quantity smaller than that of the copper oxide employed is useful, aiding the reduction of the latter. (5) The use of lead gives bad results. Two good recipes are:—

	I.	II.
Pegmatite.....	40	10
Sand.....	40	44
Chalk.....	18	12
Borax (dried).....	12	..
Soda.....	..	21.5
Cupric oxide.....	6	6
Stannic oxide.....	6	3

	Percentage after deducting of CuO and SnO <sub>2</sub> .	
	I.	II.
Silica.....	67.62	68.92
Alumina.....	7.06	6.85
Alkalis.....	7.83	17.83
Lime.....	9.87	6.39
Boric anhydride.....	8.23	..

The formation of the red colour takes place best in open vessels; during the firing strong reduction occurs, followed by oxidation and the development of blue or green tones if air be allowed access at the end of the operation. It is thought that the red colour is due, not to a cuprous silicate, but to the diffusion and solution in the glaze, of metallic copper, similar to that obtaining in the case of gold. If the ware be cooled rapidly, only a colourless glaze is produced, slow cooling being necessary to bring out the full colour.

—B. B.

*Manufacture of "Porcelaine Craquelée."* Lauth and Dutailly. Mon. Céram. et Verr. 19, 284.

THIS method of decoration is very much used by the Chinese. It may be brought about in two ways: (a) by conducting the burning at such a temperature that the expansion of paste and glaze is different; (b) by altering the composition of either. The simplest way is to modify the composition of the glaze. By increasing the quantity of alkalis the glaze becomes more easily fusible; by increasing the quantity of silica, less easily fusible; it is found practically better to increase the quantity of silica and so make the glaze more difficultly fusible. If more silica be added, the alumina must be decreased in proportion; the same result may be attained, however, by increasing the

alumina alone, although in this latter case the markings are not so regular. The authors use the following glazes:—

	"Craquelée" Glaze (Increase in Silica).	Normal Glaze.
SiO <sub>2</sub> .....	79.42	66.18
Al <sub>2</sub> O <sub>3</sub> .....	11.80	14.55
KNaO .....	5.51	3.55
CaO .....	2.88	15.90

They use a paste consisting of 66 per cent. of SiO<sub>2</sub>, 27 per cent. of Al<sub>2</sub>O<sub>3</sub>, and 7 per cent. of KNaO. The "craquelée" glaze is made from 51.5 parts of pegmatite, 38 parts of sand, 6 parts of kaolin, and 5 parts of marble. By increasing the alumina alone the following glaze may be used:—

SiO <sub>2</sub> ..... 69.92	} corresponding to	85.70 parts of felspar.
Al <sub>2</sub> O <sub>3</sub> .... 18.14		14.18 " " sand.
KNaO.... 11.95		1.42 " " kaolin.

—T. L. B.

#### PATENT.

*Improvements in and Relating to the Construction of Glass Melting Pots.* A. G. Neville, Lazeurville, U.S.A. Eng. Pat. 13,128, August 20, 1889. 6d.

The glass melting pots described in this specification are provided with a "glory-hole," an opening for the entrance of the flame, a series of air-supplying passages, a series of escape flues communicating with the pot at different levels, and a hot blast flue having communication with the pot at several points.—E. G. C.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

*Hydraulic Cements.* Dingl. Polyt. J. 273, 471—477, 551—563, and 587—600.

NEARLY the whole of the first part of this article is occupied by an account of *Candlot's* work, for an abstract of which see this Journal, 1889, 543 and 544. The rest deals with sundry alterations in the methods of testing prescribed in Germany which are of purely local interest, save that which does away with the "firing test" (*Darrprobe*, this Journal, 1889, 781) as fallacious, seeing that it may both condemn a good cement and allow a bad one to pass.

The committee of the Association of German Cement Makers points out that the rules for testing Portland cement are only applicable to that material, and will not serve to compare other kinds of hydraulic cement with each other.

R. Dyckerhoff, at the general meeting of the Association of German Cement Makers, discussed the various methods of preparing test-pieces. When these were universally made by hand both tension and compression specimens had the same density; but when they began to be prepared by the Böhme hammer apparatus, 150 blows with a 2-kilo. hammer being used in each case, it was plain that as the compression specimens attained the same density as those prepared by hand, the tension test-pieces must have a greater density, as their bulk was only one-fifth as great. If fewer blows were used (*e.g.* 30) so as to get the right density, the tensile strength fell considerably short of the hand-gauged test-pieces. These facts are well shown by the following table:—

1 Cement : 3 Normal Sand.

Mark.	Method of Preparation.	Water used.	Specific Gravity.		Strength, 28 days.	
			Tension.	Compression.	Tension.	Compression.
		Per Cent.				
A.	Hammer apparatus, 150 blows .....	10	2.304	2.226	22.1	224.0
A.	By hand.....	10	2.228	..	22.4	..
A.	Hammer apparatus, 30 blows .....	10	2.232	..	18.6	..
B.	Hammer apparatus, 150 blows.....	10	2.304	2.236	20.5	193.6
B.	By hand.....	10	2.235	..	20.6	..
B.	Hammer apparatus, 30 blows .....	10	2.228	..	15.6	..

From this it appears that the density of the test-pieces is a gauge of their right preparation only when the specimens compared have been made by the same means, and in the same manner.

Böhme has experimented with his own apparatus on the influence of the number of blows used, on the density and tensile strength of briquettes:—

1 Cement : 3 Normal Sand.

No.	Mode of Preparation.	Average Weight.	Corresponding Density.	Mean Tensile Strength at Seven Days.
I.	By hand .....	160.6	.. .. .	Kilos, per Sq. Cm. 16.06
II.	Hammer apparatus, 75 blows.....	158.0	2.225	12.75
III.	" " 100 " .....	159.5	2.246	13.25
IV.	" " 125 " .....	159.5	2.246	14.56
V.	" " 150 " .....	159.0	2.239	15.56

The apparently greater tensile strength of the hand-gauged briquettes, when compared even with those prepared by 150 strokes in the hammer apparatus, may be due to some subsidiary factor, such as the trimming and smoothing off of the cement in the mould, and not to any innate superiority in the process.

Schumann has noticed that cubical test-pieces for compression tests exhibit a somewhat greater strength when allowed to harden in the mould than when taken out earlier, the difference amounting to 17–34 kilos. per sq. cm., but following no discernible law. Böhme observed a maximum difference of 11 kilos., while Schott attributes the phenomenon to the variation in the quantity of moisture present, and points out that with soft cement mortars true cubes are not obtained, but in their place slightly rhombohedral masses. The Association accordingly resolved that the test-pieces shall not be withdrawn from the moulds until 24 hours after gauging have elapsed.

Schiffner discoursed on the testing of quick-setting cements by the standard rules. Such cement gives a lower tensile strength than it actually possesses on account of its setting to some extent during gauging. He counselled the use of a temperature not greater than 15°–18° C. (compare Candlot's researches in this direction, this Journal 1889, 544), and proposed in the case of cements setting too quickly, even at this temperature, to abandon the use of the hammer apparatus in favour of hand-gauging and the use of quantities of material only sufficient for one or two briquettes at a time. The neglect of these precautions leads to the tensile strength of test-pieces prepared by the machine to be about two-thirds only of that of the specimens prepared by hand.

Some means of checking the predetermined composition of the mortar on the spot where it is to be used as a building material is very desirable, and P. Goloubiatnikow has devised the following plan:—100 grms. of the neat cement are passed through a sieve having 900 holes per sq. cm., and the quantity and therefore percentage of the portion that passes through, determined: this is called *a*.

The sand with which it is to be mixed is similarly treated and the result termed *b*. One hundred grammes of the mixed sand and cement awaiting use at the works are then dealt with in the same way, and the portion which passes through the sieve weighed and called *M*. Then calling the unknown quantities of cement and sand in the mixture *C* and *Z* respectively, we have—

$$C + Z = 100$$

and

$$\frac{a}{100} C + \frac{b}{100} Z = M.$$

Hence—

$$C = \frac{100(M-b)}{a-b} \text{ and } Z = \frac{100(M-a)}{b-a}.$$

By this simple method results of a considerable degree of exactitude can be obtained, the total maximum experimental error being 4.5 per cent.

If  $a = b$ , a sieve with a different mesh must be used. The process is said to be applicable to mortar that has been wetted for use; more water is added until the consistency is that of a thin paste, which is then evaporated to dryness with constant stirring over a naked flame, and dealt with as above; it is asserted that the size of the cement particles is unaltered by this treatment.

The sintering points and relative fusibility of cements have been studied by M. Meyer, who experimented with six samples of slurry and found them all run down to a slag below the temperature at which Seger's standard cone No. 15 melts.

By using definite quantities of fuel to produce given temperatures it was found that the consumption of 1,100 grms. of coke (in a Senfström furnace) yielded a temperature high enough to give a porous appearance to all the test-pieces, while when 1,150 grms. were burned, complete fusion took place. The six samples of slurry,

ranged from the most to the least fusible, had the following percentages of calcium carbonate:—

No. 1.....	76.6
No. 2.....	76.2
No. 3.....	75.2
No. 4.....	76.3
No. 5.....	77.4
No. 6.....	78.8

Nos. 1 and 2 contained much ferric oxide, No. 3 much magnesia.

In order to gain some knowledge of the influence of the percentage of lime on the heat of saturation of a cement by hydrochloric acid, a calorimetric investigation was instituted. An Erlenmeyer flask was well protected from the reception or emission of heat in the ordinary way, 20 grms. of normal sand previously washed with acid introduced, and 250 cc. of 10 per cent. hydrochloric acid added. The whole apparatus was brought to the temperature of the room, the thermometer it contained (graduated to 0.05° C.) read off, and the cement to be tested (1 gm.) reduced to the finest possible powder thrown in, the whole well mixed and the thermometer again read when it ceased to rise. The water-value of the apparatus as well as the correction for loss by radiation, were determined by performing an experiment with warm water only, and also with pure lime. The six cements ranged in the order of their fusibility gave the following figures:—

Order of Fusibility.	Rise of Temperature.	Lime.
	° C.	Per Cent.
1	1.76	60.3
2	1.77	61.1
3	1.78	61.1
4	1.82	63.8
5	1.80	65.3
6	1.80	67.7

It appears therefore that the rise increases with the percentage of lime. It has been further established that the harder a cement has been burnt the less heat it evolves in its reaction with acid: e.g., an irregularly burnt piece of clinker was divided into three parts according to the temperature it had been locally subjected to; the under-burnt portion gave a rise of temperature of 2° C. for 1 gm., the next, one of 1.94° C., and the thoroughly burnt, 1.82° C. As the final products of the reaction of the cement and acid are the same in all three cases, it is plain that an evolution of heat by the clinker occurs in the kiln when it is burnt at a higher temperature.

Blast furnace slag tested by the same method gave, before granulation, a rise of temperature of 0.8° C., and when granulated, 1.8° C. This, therefore, may be used as a method for detecting sophistication of Portland cement with slag.

#### *Action of Air, Fresh Water, Sea-Water, and Frost on Cement.*

(a) *Before use.*—Tomäi has come to the following conclusions:—

- (1.) Test-pieces of neat cement are best for the study of the action of the air.
- (2.) Dry carbonic anhydride is not sensibly detrimental, and may be advantageous in some cases.
- (3.) The prolonged action of moist air is certainly deleterious. During the experiments from which these deductions are drawn it was incidentally determined that the so-called "Nachfeinen" did not take place, as no difference in the fineness of the cement before and after exposure could be detected; it was also found that the rise of temperature decreased in proportion to the extent to which moist air had acted on the cement. The practical upshot of all this is that aeration is harmless or even beneficial if rationally conducted, but most injurious in the contrary case.

(b) *After use.*—It is of importance to ascertain the behaviour of cement under various conditions of hardening, considering its bearing upon actual work. R. Dyckerhoff has found that test-pieces put under water less than 24 hours after gauging show but little deviation in strength in compression from others treated in accordance with the standard rules. The time limit is fixed by the rapidity with which the cement sets; quick-setting cements can be immersed after the lapse of six hours or even less.

The following experiment serves to show the influence of water pressure on cement while it is hardening:—A tank, 2 m. + 50 cm. + 2 of brick, half a brick thick, was built, using a mortar consisting of one of Portland cement to three of sand. After a few days it was filled with water and found to leak at the lower part of the sides and bottom; the water was then drawn off and one side lined with a mixture of one of cement to one of sand, covered with neat cement, when it was found to be water-tight. An attempt was made to coat the three other sides while under water, but without

success, as the cement only stuck to the upper third of the tank. At a certain pressure the cement had no tendency to harden at all. It is therefore best to keep water off cement while setting, but if this be impracticable, recourse may be had to a quick-setting cement (1:1), or a mixture of the usual composition (1:3), to which has been added one-fourth part of slaked lime, thus decreasing the time of setting to a quarter of an hour. The results of a series of experiments made with a cement of ordinary strength, which set in five hours, and of which the test-pieces had been prepared in the standard way, demonstrated that the highest tensile strength at the end of a year is attained by exposure in the open air after the first 24 hours.

If either kept under water or in a dry atmosphere the figures are considerably lower. Thus Portland cement may be looked upon as pre-eminently an aerial mortar.

The appended table shows the effect of sea-water on cement both gauged with it and allowed to harden in it:—

Mark.	Time of Setting.	Tensile Strength. Kilos. per Sq. Cm.							
		Gauged with, and kept in, Fresh Water.		Gauged with Fresh Water, kept in Sea-water.		Gauged with Sea-water, kept in Fresh Water.		Gauged with, and kept in, Sea-Water.	
		1 Week.	4 Weeks.	1 Week.	4 Weeks.	1 Week.	4 Weeks.	1 Week.	4 Weeks.
A	8	20.9	26.7	18.6	25.1	17.1	24.8	16.9	23.2
B	6	..	25.6	17.5	22.4	..	22.8	15.5	20.6
C	6	18.1	23.6	16.7	21.2	14.9	20.5	15.3	19.3
D	6	15.6	21.1	13.8	19.3	11.4	18.0	11.0	17.7
E	$\frac{1}{2}$	15.4	20.4	14.9	18.6	12.9	17.1	12.0	17.0

The general effect of the sea-water is to lower the tensile strength; if used for gauging the cement it makes this effect most felt; the use of fresh water in practice should therefore be insisted on. A quick-setting cement suffers less, as the infiltration of the sea-water and the destructive double decomposition taking place between the lime in the cement and the magnesium salts in the sea-water, is sooner stopped.

The comparative harmlessness of sea-water acting on cement from without appears contradicted by the experiments of Professor Brazier, of Aberdeen, and by the failure of the breakwater at that place. The former were, however, conducted on a scale and under conditions which prevent their bearing directly on actual work, while the latter cannot reasonably be attributed to any specific and inevitable action of sea-water on Portland cement. The breakwater was constructed as follows:—Bags of concrete (1 part of cement, 2½ parts of sand, and 3½ parts of gravel), weighing about 100,000 kilos., were deposited at the bottom of the sea and levelled by divers. On these were built concrete blocks (1 part of cement, 4 parts of sand, and 5 parts of gravel), previously made and allowed to harden in the air, and heavy stones. The blocks weighed in the first instance 7,500—18,000 kilos., and were afterwards increased to 10,000—24,000 kilos.; they were built up with open joints to a height of 8 m., 30 cm. above low-water mark. Above these was built a layer of concrete run in between temporary retaining boards *in situ*, consisting of 1 part of cement, 3 parts of sand, and 4 parts of gravel. The mean thickness of the whole structure was 12 m.; all the materials were of good quality. After some years signs of destructive action were observed. In heavy weather single blocks of concrete were torn away, and through the gaps thus left the sea entered and did further mischief. A creamy paste appeared in various cracks and crannies, which was found by Brazier to consist of magnesia and calcium carbonate.

German manufacturers assign this failure to mechanical causes. They consider that the concrete blocks were too small, and that the cement was used too sparingly. Schumann advocates a mixture not poorer than 1 part of cement, 2 parts of sand, and 3 parts of gravel, where

work is exposed to the direct action of the sea. Portland cement has been freely used in Germany for harbour work, and failures are quite exceptional, and can then be traced to the use of bad material.

With regard to the action of frost on cement, Froideville and Schott remark on the fact that cement gauged with excess of water exfoliates when exposed to frost, the solidification of the water in excess of that necessary for the setting of the cement being the cause. Other observers, and notably Bohme (for an abstract of whose work see this Journal 1889, 393), agree that frost has little permanent ill effect on Portland cement used with reasonable care.

Dyckerhoff, Seger, and Delbrück are agreed that the addition of salt to Portland cement is baneful, but consider it requisite for Roman cement and lime mortar. Goerke states that the use of sand containing salt is prohibited at Norden on the Baltic.

Dyckerhoff has experimented on the behaviour of various hydraulic cements under different conditions of hardening, and records his results in the appended table:— (See top of page 72.) Normal sand was used throughout, and the samples were, without exception, gauged by means of the Bohme hammer apparatus, using 150 strokes.

Schumann found, in comparing Portland cement with puzzolana cement, that the latter suffered more from the action of frost than the former, and that it was altogether a weaker material. Like trass cement it consists of a mixture of acid silicates and lime, which combine to form cementitious basic silicates when brought into contact with water, thus offering a contrast to Portland cement, which has been brought to such a composition in the kiln that it combines directly with the water added to it. This accounts for the fact that puzzolana and trass cements harden better under water than they do in air.

According to L. Tetmaier, cements free from any tendency to alter in volume after setting do not exist; they all expand in water and contract in air. It is essential to note the above facts in testing this property, and to eschew such crude tests as that consisting in filling a thick-walled

Nature and Composition of Sample	Standard Tests.			Tensile Strength. Kilos. per Sq. Cm.

CaCO <sub>3</sub> .....	Trace.	..	1.34	7.52
CaSO <sub>4</sub> .....	3.16	..	1.93	1.85
MgO .....	1.95	3.76	0.83	0.81
H <sub>2</sub> O .....	1.63	3.05†	2.13	2.66
SO <sub>3</sub> .....	..	0.75	..	..

\* Analysis of sample C after remaining three months in sacks.  
† H<sub>2</sub>O and CO<sub>2</sub> = 3.05.

A became brittle and friable in two years; it then contained 8.75 per cent. of CO<sub>2</sub>. B had a tensile strength of 22 kilos. per sq. cm. after 84 days, and disintegrated in a year and a half. C failed in three months, but if previously exposed in sacks for three months (see note to D) it was permanent in air; it was also permanent in water without previous aëration. It therefore appears that the ultimate composition is not the reason for the expansion of the samples, but it must be ascribed to a want of homogeneity in the raw materials, together with imperfect firing, causing the formation of unstable bodies of little cementitious value, and readily decomposed by CO<sub>2</sub> to form CaCO<sub>3</sub>, thereby setting up a gradual expansion as the air acts from the outside upon the cement.

Cements which fail by expansion under water fall into three classes:—(a) Those containing easily oxidisable bodies, e.g., CaS, which expand on oxidation. One per cent. of CaS is injurious in Portland cement, but cement from blast-furnace slag may apparently contain as much as 5 per cent. without detriment. (b) Those containing free lime on account of imperfection of mixing. (c) Those, which although properly mixed and burned, contain too much free lime, magnesia, or calcium sulphate. The "firing test" ("Darrprobe," this Journal, 1889, 781) will detect the free lime, but not the calcium sulphate.

An account is given of the failure of the cement on *Stephan's Dome* in Vienna, for an abstract of which see this Journal, 1889, 781.

*Influence of Foreign Matters on Cement.*—Coloured plates of Portland cement made by mixing pigment with the cement, have sometimes failed from the action of the pigment on them; thus a red pigment containing 22 per cent. of sulphuric acid (2 free) caused the disintegration of a plate into the composition of which it entered to the extent of 17 per cent., owing to the formation of calcium sulphate. Magnesia, if present in such quantities as 16 to 18 per cent., brings about the destruction of cement by expansion.

For *Dyckerhoff's* researches in this direction see this Journal, 1889, 781.

*Candlot* has investigated the action of solutions of calcium chloride of various strengths on the setting of Portland cement, with the following results:—

CaCl <sub>2</sub> per litre (grms.)...	0	2	5	10	20	40	60	160	200	300
Time of setting (hours)...	25'	1	10	10	12	80	6	20'	9	8'

Thus the first effect is to retard it greatly, but a maximum is reached, varying with the cement used, between 10 and 40 grms. per litre. At a concentration below 60 grms. per litre, the normal formation of hexagonal plates of Ca(OH)<sub>2</sub> takes place, and the CaCl<sub>2</sub> is inert chemically. Above 100 grms. long needles of calcium oxychloride form, and the time of setting drops abruptly from six hours to 20 minutes. Bearing on this phenomenon is the solubility of Ca(OH)<sub>2</sub> in solutions of CaCl<sub>2</sub> of various strengths.

CaCl <sub>2</sub> per litre (grms.) .....	0	15	36	61	100
CaO dissolved per litre (grms.) ..	1.298	1.003	1.032	1.121	1.312

The fluctuation is quite comparable with that of the time of setting.

*Rinne* disputes *Candlot's* conclusions, and considers his deduction that calcium chloride in concentrated solutions retards the setting to be based on an error; he opines that *Candlot* used too little of the solution to allow of the proper hydration of the cement, having regard also to the avidity of CaCl<sub>2</sub> for water.

W. Michaelis advocates the judicious addition of finely-ground slag to Portland cement. Comparative experiments, extending over five years, on a cement of high quality, with and without the addition of 25 per cent. of slag, showed that the mixture possessed a higher strength, both in tension and compression, than the pure cement.—B. B.

*Hardening of Portland Cement.* Schöffner. Deutsche Töpfer u. Ziegler Zeit. 20, 597.

The author considers that the chief cause of the occasional failure of this mortar to harden is either presence of an excess of water during the mixing, or a want of moisture through premature desiccation.

From a series of experiments, the author concludes that mortar which has been kept damp for 24 hours after mixing, hardens perfectly when placed under water. On the other

hand, if left without any such precaution, the mortar becomes more or less tender.

It is therefore essential to keep the mortar damp for the first few days after preparation.—S. B. A. A.

*The Action of Air and other Gases on Cement.* Tomäi. Deutsche Töpfer u. Ziegler Zeit. 20, 697.

FRESHLY-GROUND cement was found to have a specific gravity of 3.162, and a weight per litre of 1,250 grms. After 28 days' storage these numbers were 3.154 and 1,242 grms. respectively, and after 90 days' exposure to air, 3.128 and 1,225 grms. Dry air, free from carbonic acid, dry carbonic acid, and especially moist carbonic acid free air, diminish the weight of cement. As regards the strength of cement, dry carbonic acid was found to exert a favourable influence, both the tensile and compressive breaking stress being increased. Dry air has a similar effect. Moisture weakens cement; a cement which tested at first 17.8 kilos. tensile breaking stress, and 201 kilos. compressive breaking stress, required, after 28 days' exposure to moist air, only 13.5 kilos. and 143 kilos. respectively. Sulphuretted hydrogen and calcium sulphide have but little influence on the specific gravity and weight per litre of cement, but the heat produced on mixing with water is diminished, and the time required for the cement to set is increased. The surface of fracture was found to have a greenish tint, due, no doubt, to the formation of sulphide of iron. The strength diminished from 17.8 kilos. tensile stress and 201 kilos. compressive stress to 12.9 kilos. and 137 kilos. respectively, after 28 days' exposure to sulphuretted hydrogen, and to 14.3 kilos. and 158 kilos. respectively, by the addition of 1 per cent. of calcium sulphide. The author is of opinion that the degree of heating and the time of setting of a cement depend on the aluminates and ferrates present in it, since these are the only bodies likely to be affected by the addition of calcium sulphide.—H. T. P.

*The Permeability of Roofing Tiles.* R. Boute. Thonind. Zeit. 1889, 13, 611.

THE natural porosity of roofing tiles, although useful in favouring the adherence of mortar, is objectionable inasmuch as it allows the percolation of rain-water, especially on slightly-sloping roofs. Glazed tiles are little better than the common kind, as the least flaw lets in water, which, once in, saturates the tile, and cannot freely evaporate because of its glazed surface. A better plan consists in giving the tiles, before burning, a clayey coating, by which their porosity is unimpaired while their permeability is much diminished. The same effect may be produced by steaming the tiles, and filling their pores with graphite. Roofs already existing may be protected by coal-tar or beet molasses. Besides the direct action of the latter, due to its gelatinous character, is the aid afforded by the dead mycelia of moulds which flourish during its change to acetic acid.—B. B.

*Portland Cement Concrete.* V. Brausewetter. Thonind. Zeit. 1889, 13, 624.

THE failure of concrete cast *in situ* (leaving out of consideration those cases in which a cement with a natural tendency to expand and disintegrate has been used) may be attributed either to error in its preparation or to the use of hydraulic lime in place of Portland cement. With regard to the former, it must be remembered that the least possible quantity of water should be used, as a needless excess causes abnormal expansion while setting, followed by considerable contraction. Mixtures not too rich in cement should be employed, a lesson to this effect being taught by the case of "Stephansdom" (this Journal, 1889, 781). Milk of lime is preferable to plain water, as capillary cracks are thus avoided. A sand of low specific gravity is desirable, to obviate the risk of separation from the rest of the concrete by subsidence, owing to its being necessarily of somewhat thin consistency.—B. B.

*Damaged Asphalt Paving.* W. Dehnhardt. Centralbl. f. Bauverwalt. 9, 94.

AN asphalt street pavement which had been laid down 2½ years previously, was found to be much damaged. Soon after being repaired, faulty places again appeared. The damaged places were soft, and saturated with a kind of tar, and exhibited on the surface a number of radiating fissures 2—3 cm. deep. This peculiar appearance was found to be due to an escape of illuminating gas from pipes laid underneath the pavement. The heavy hydrocarbons, and especially the benzene, contained in the gas, were absorbed by the asphalt, rendering the pitch contained in the latter soft, and thus destroying the coherence of the mineral portion of the pavement.—H. T. P.

PATENTS.

*An Improved Process for Hardening, Preserving, and Preparing Oolitic and other Limestones.* G. J. Randall, Tooting Graveney. Eng. Pat. 15,041, October 19, 1888. 4d.

THE limestone is heated and then immersed in a solution of milk of lime, acetic acid, and cane sugar molasses. The stone so treated is next rubbed to a face with fine grit, and allowed to dry in the atmosphere, after which it is dried at a moderate temperature, and allowed to cool slowly.

—E. G. C.

*Process for the Crystallisation of Silica in a Compacted Mass.* A. C. Ponton, Parkstone, B. L. Mosely, Hastings, and C. Chambers, Hastings. Eng. Pat. 15,256, October 23, 1888. 6d.

"LIGHT silicas" are powdered, mixed with water, and in this condition compressed into moulds and exposed to the heat of a porcelain kiln.—E. G. C.

*Improvements in Apparatus for Calcining Cement Materials, Hydraulic Lime, Plaster of Paris, and like Substances.* J. W. H. James, Westminster. Eng. Pat. 16,234, November 9, 1888. 8d.

THE inventor claims a rotating drum, so constructed that the flames and products of combustion, and substances to be calcined, all travel in the same direction; also an annular fuel supply way, and central feed way for substances to be calcined. Other claims are detailed at length in the specification.—E. G. C.

*Improvements in Artificial Stones or Blocks applicable for Grinding, Crushing, Granulating, Polishing, and other similar Purposes.* C. O. Weber and F. W. Follows, Manchester. Eng. Pat. 16,770, November 19, 1888. 6d.

THE base or bulk of the stone or block is formed of ground or granulated flint, or granite, while the face or grinding surface is preferably made of granulated emery, corundum, or other hard abrasive material. The cementing mixture contains oxide of magnesium, hydrochloric acid, sulphate of iron, and chloride of barium.—E. G. C.

*Improvements in Colouring and Ornamenting Portland Cement for the Manufacture of Imitation Grained or Figured Marble, Mosaics, Ornamental Slabs, Tiles, and other Forms, either Plain or in Mixed Colours.* W. Cussans, London. Eng. Pat. 17,257, November 27, 1888. 6d.

AMONG the materials used in admixture with the Portland cement are the oxides of iron, copper, manganese and chromium, also chalk, barytes, brass turnings, copper borings and tin filings.—E. G. C.

*Improvements in the Manufacture of Cement and in Apparatus employed therein.* J. Hargreaves, T. Robinson, and J. Hargreaves, Widnes. Eng. Pat. 17,363, November 29, 1888. 8d.

THE following claims are made:—

- (1.) For mixing slurry by giving a "circular rotating or return motion" to the raw materials ("lime, clay, and water") by means of air or other suitable gas. For this an apparatus is used consisting of a closed vessel with a conical bottom, and capable of withstanding considerable pressure, through the cover of which passes a pipe conveying the agitating gases, and which is provided with an exit a little above the bottom for the fine slurry, and one at the extreme bottom for the coarser particles.
- (2.) For a filter for slurry, consisting of two concentric vessels, the inner of which is perforated and covered with filter cloth. The slurry is forced into the annular space between them, and the water flows through the filter cloth into the inner vessel, and so away.
- (3.) For a continuous filter for slurry, consisting of a closed conical vessel, having perforated walls covered with filter cloth set in any convenient position, into the larger end of which the slurry is forced, emerging at the smaller end, the water passing away through the sides of the vessel. The semi-dry slurry is cut into briks as it comes out, and is carried by an endless band through a drying oven.
- (4.) For drying slurry when it is intended to be burnt by the cylinder process, by means of a tower containing a vertical shaft bearing scrapers which pass over the surface of annular trays or shelves concentric with it. The slurry is fed in at the top, and falls from shelf to shelf, being stirred by the scrapers while exposed to a current of hot gases, preferably the waste product of the burning process,—excess of oxygen being avoided when it is desired to eliminate free sulphur from the slurry.
- (5.) For "weathering" ("aërating") the finished cement by means of an artificial atmosphere of carbon dioxide or that gas together with aqueous vapour, and for an apparatus therefor essentially similar to that described under (4). The carbon dioxide may be obtained from the waste gases of kilns, &c., cooled and freed from soot by passage through a scrubber.—B. B.

*Improvements in Apparatus for Use in the Preparation of Slurry for the Manufacture of Cement and in Mixing Slurry with Fuel.* W. Joy, Northfleet. Eng. Pat. 18,491, December 18, 1888. 1s. 1d.

THIS invention relates to improvements in the arrangements of the bars of the grids or gratings of the exits of the wash mills, and to means by which the flow of slurry to the mill-stones is automatically controlled. For details the specification with its nine sheets of drawings must be consulted.—E. G. C.

*A Weather- and Acid-Proof Enamel for Building Materials and the like, and a Method of Producing the Enamel.* J. Stiel, Cologne, Germany. Eng. Pat. 8597, May 23, 1889. 4d.

THE following ingredients are used:—Potash, soda, cryolite, apatite, fluorspar, and minium. Oxides are added according to the colour required, and the mixture is melted in a suitable furnace.—E. G. C.

*An Improved Composition for Covering Walls and the like.* G. F. Redfern, London. From J. G. Maardt, Copenhagen, Denmark. Eng. Pat. 11,922, July 26, 1889. 4d.

A Mixture of 75 parts of carbonate of lime and 25 parts of kaolin is made into a stiff paste with water, calcined, pulverised, and combined with 5 parts of calcined magnesite.—E. G. C.

*Improvements in Utilising the Waste Product from Sewage Works for the Manufacture of Bricks, Tiles, Quarries, Building Blocks, Slabs, and the like.* T. Shaw, Manchester. Eng. Pat. 12,623, August 10, 1889. 4d.

THE sludge is mixed with an equal quantity of clay. The plastic compound formed is dried and burnt.—E. G. C.

*Improvements in the Process of Treating Cements and Hydraulic Limes.* S. Jørgensen, Faxe Ladeplads, Denmark. Eng. Pat. 14,281, September 10, 1889. 4d.

BLAST-FURNACE slag moderately low in lime, or natural products of similar composition, are treated with sulphuric acid in proportion to be determined by trial, 40 lb. of slag to 25 lb. of sulphuric acid being suitable normally. A dry grey powder is thus obtained, consisting of free silica and metallic sulphates which may be added to the extent of 1·7 per cent. to good Portland cement, 3·3 per cent. to inferior qualities, and 3·5 to 7·0 per cent. to slag cement, increasing, it is alleged, their hardening properties.—B. B.

*Improvements in Waterproof Slabs and Blocks for Structural Purposes.* D. Nicoll, London. Eng. Pat. 14,733, September 18, 1889. 4d.

ONE or more of the bituminous substances described by the patentee in previous patents of dates ranging from February 5th, 1866, to May 11th, 1887, are mixed with grit, shingle, sand, or chalk, and the compound cast into moulds shaped so as to form tenons and mortises; the blocks thus produced are placed one above the other so that the tenons and mortises correspond, a space being left sufficient to allow a flame from such a source as a spray of mineral oil to play between them, and fuse them together. By this means large blocks may be built up, which may be used for sea walls, tunnels, &c.—B. B.

*Improvements in the Manufacture of Artificial Asphalt.* J. Erslev, Copenhagen, Denmark. Eng. Pat. 15,669, October 5, 1889. 4d.

EIGHTY to 90 parts of resin ("Resina pini flava") are melted together with 20 to 10 parts of coal-tar ("Pyrooleum lithanthracis") and 100 parts of sand or clay, and 200 to 400 of rough gravel added. The product may be used in the same way as natural asphalt, than which it is said to be better and cheaper.—B. B.

## X.—METALLURGY.

*Preparation of Manganese from Manganese Chloride and Magnesium.* E. Glatzel. Ber. 22, 2857—2859.

CRYSTALLISED manganese chloride is first dehydrated in a porcelain basin, powdered and 100 grms. of the powder mixed with 200 grms. of dry powdered potassium chloride.

This mixture is brought into a Hessian crucible stamped down, closed with a loose lid and melted down in a wind furnace. A moderate heat only is requisite. The crucible is now withdrawn and 15 grms. of magnesium thrown in in pieces of 3 to 4 grms. at intervals of two to three minutes.

The fused mass should not be heated to too high a temperature before the addition of the magnesium, otherwise the reaction is so violent that the contents of the crucible are thrown about. A dull red heat necessary to keep the mass molten is sufficient.

The crucible is now covered with the lid and returned to the furnace, heated strongly again, and allowed to cool in the furnace. On opening the crucible a lump of manganese is found weighing from 20 to 25 grms.

The metal thus obtained has a metallic fracture, which does not oxidise in dry air, is non-magnetic, and has a specific gravity of 7·3921 at 22°.—J. B. C.

*On the Hardening and Tempering of Steel.* W. C. Roberts-Austen. A Lecture before the British Association, Newcastle-on-Tyne, 1889.

This lecture is as perfect and comprehensive a consideration of the subject as it is possible to obtain in the space at the disposal of the author. The first part is devoted to the opinions expressed by the various writers from the earliest periods down to the present day. Each branch of the subject is treated historically, and full references are given to all the works of the writers quoted. After this extensive retrospect, the author proceeds to discuss in more detail the more recent researches and theories. In referring to the confusion at present existing in the use of the words "hardening," "tempering," and "annealing," he gives the following definitions:—"Hardening" is the result of rapidly cooling a strongly heated mass of steel; "tempering" consists in re-heating the hardened steel to a temperature far short of that to which it was raised before hardening—this heating may or may not be followed by rapid cooling; "annealing" consists in heating the mass to a temperature higher than that used for tempering, and allowing it to cool slowly.

The hardening and tempering of steel is largely the result of the form which the carbon therein is made to assume, but the main facts are not fully explained by the change in the mode of existence of the carbon.

It is possible to obtain a perfectly soft steel by rapid cooling from a certain temperature, in which the carbon is shown by analysis to exist as "hardening carbon." Further explanations are forthcoming by the assumption of the existence of allotropic forms of iron. The consideration of this important branch is entered into at some length.

Chernoff showed that steel could not be hardened by rapid cooling until it had been heated to a definite temperature—to a degree of redness which he called  $\alpha$ .

Gore found that a molecular change could be produced by heating an iron wire, which exhibited a momentary elongation during cooling.

Barrett discovered that an iron wire suddenly glows at a certain stage during cooling, a phenomenon which he designated "recalescence."

In 1879 Wrightson called attention to the abnormal expansion of carburised iron at high temperatures. Pionchon showed that at 700° the specific heat of iron is altogether exceptional, while Le Chatelier detected that at the same temperature a change occurs in the curve representing the electro-motive force of iron; both of these latter experimenters concluding that they had obtained evidence of the passage of iron into an allotropic state. Osmond in his quite recent researches has studied by the aid of a chronograph the molecular changes which take place in pieces of iron and steel during slow heating and slow cooling, using as a thermometer a thermo-electric couple of platinum and of platinum containing 10 per cent. of rhodium, converting the indications of the galvanometer into temperatures by Tait's formulae. A mass of electro-deposited iron in cooling from 2,000° to 870° falls uniformly at the rate of about 2.2° a second, but at 858° there is a break and 26 seconds are absorbed while the temperature falls through an interval which previously would have occupied six seconds, after which the temperature again decreases uniformly. In the case of mild steel there are two such breaks, each of which occurs at a temperature different to that in the case of pure iron. With higher carbon steels the two breaks gradually get nearer to one another until they coalesce in the case of steel containing 1.25 per cent. of carbon, the single break in this instance lasting 76 seconds at a temperature of about 680°.

"Now, it may be urged, evidently the presence of carbon has an influence on the cooling of steel when left to itself; may it not affect molecular behaviour during the rapid cooling which is essential to the operation of hardening? We know that carbon, during rapid cooling, passes from the state in which it is combined with the iron into a state in which it is dissolved in the iron; we also know that during slow cooling, this dissolved carbon can re-enter into combination with the iron, so as to assume the form in which it occurs in soft steel. Osmond claims that this

second arrestation in the fall of the thermometer corresponds to the recalescence of Barrett, and is caused by the reheating of the wire by the heat evolved when carbon leaves its state of solution and truly combines with the iron." If it is desired to harden steel the metal must be rapidly cooled before its temperature has fallen to 650°, otherwise the presence of carbon will be unavailing. A break occurs, however, in electro-deposited iron containing no carbon, a break indicating an evolution of heat with which carbon has nothing to do, and which must indicate therefore some molecular change in the iron itself. "Osmond argues thus: There are two kinds of iron, the atoms of which are respectively arranged in the molecules so as to constitute hard and soft iron, quite apart from the presence or absence of carbon. In red-hot iron the mass may be soft, but the molecules are hard, let us call this  $\beta$ -iron; cool such red-hot pure iron, whether quickly or slowly, and it becomes soft; it passes to the  $\alpha$  soft modification, there is nothing to prevent its doing so. It appears, however, that if carbon is present, and the metal be rapidly cooled, the following result is obtained: a certain proportion of the molecules are retained in the form in which they existed at a high temperature—the hard form, the  $\beta$  modification—and hard steel is the result."

"This molecular change from  $\beta$ -iron to  $\alpha$ -iron during the slow cooling of a mass of iron or steel is, according to Osmond's theory, indicated by the first break in the curve, representing the slow cooling of iron, as is proved by the fact that it occurs alone in electro-iron. A second break, usually one of much longer duration, marks the point at which carbon itself changes from the dissolved or hardening carbon to the combined carbide-carbon. It follows that if steel be quickly cooled after the change from  $\beta$  to  $\alpha$  has taken place, but before the carbon has altered its state—that is, before the change indicated by the second break in the curve has been reached—then the iron should be soft, but the carbon, hardening carbon; and as such, the action of a solvent should show that it cannot be released from iron in the black carbide form. This proves to be the case, and affords strong incidental proof of the correctness of the view that two modifications of iron can exist. It will be seen, therefore, that although the presence of carbon is essential to the hardening of steel, the change in the mode of existence of the carbon is less important than has hitherto been supposed."

The experiment was then shown of heating a bar of high-carbon steel to redness, fixing it in a horizontal position at one end and hanging on to the other a weight insufficient to bend it when at its hottest. The bar remained straight as it cooled until a certain point was reached, when it commenced to bend slightly before becoming permanently rigid. This point has been found to coincide with that at which, according to Osmond's theory, molecular change takes place, and in this instance, being a high-carbon steel, at that point also at which the hardening carbon changes into carbide-carbon. Advantage has been taken of this fact to straighten distorted steel axes.

An experiment was also shown to demonstrate the weldability of steel in the Bunsen burner. The two ends of a newly fractured steel rod were placed together, covered with platinum foil to exclude air, and heated in a Bunsen flame. The metal welded without pressure, so that it was difficult to break with the fingers, although the temperature had not attained a red heat.

As regards the behaviour of other metals on iron, Osmond has shown that manganese enables steel to harden very energetically, and that when 12 to 20 per cent. is present there is no break whatever in the curve representing slow cooling. The iron shows no sign of any change such as occurs in other cooling masses of iron, and it may be assumed that it remains in the  $\beta$  condition. If this be so then manganese-iron alloys should be hard whether they are cooled rapidly or slowly, and this is found to be the case. Again "red-hot iron is non-magnetic. Hopkinson has shown that the temperature of recalescence is that at which iron ceases to be magnetic. It may be urged that  $\beta$  iron cannot therefore be magnetised. Steel containing much manganese cannot be magnetised, and it is therefore fair to assume that the iron present is in the  $\beta$  form." When small

quantities of manganese are present the change of form of the iron is not altogether prevented but is retarded.

"Tungsten possesses the same property as manganese, but in a more marked degree. Chromium has exactly the reverse effect, as it enables the change of hard  $\beta$  iron to a soft iron to take place at a higher temperature than would otherwise be the case, and this may explain the extreme hardness of chromium steels when hardened in the same way as ordinary steels."

The points *a* and *b* of Chernoff change in position with the degree of carburisation of the metal, and in a highly carburised steel the point *a* corresponds to that point at which Osmond considers that iron in slow cooling changes from the  $\beta$  to the  $\alpha$  modification. It is impossible to harden steel by rapid cooling after the temperature has fallen below *a*. If steel be heated to a temperature above *a* but below *b*, it remains fine-grained however slowly it is cooled. If it be heated above *b* it assumes a crystalline granular structure whatever may be the rate of cooling. The crystalline structure is destroyed by forging. The quenching in oil of large masses of steel also seems to break up the crystalline structure. In such cases the metal is hardened only at and near the surface, but the cooling of the interior is more rapid than otherwise would be the case and the formation of large crystals is arrested. This prevention of crystallisation the author believes to be the great merit of oil quenching, which, as regards large masses of metal, is certainly not a true hardening process.

The metal of a complicated steel casting probably contains much hardening carbon, and the mass is crystalline. The effect of annealing is to permit the change of carbon from the hardening to the carbide form and incidentally to break up the crystalline structure, with the result that a stronger and more extensible casting is obtained.

"Looking back over all the facts, it will be evident that two sets of considerations are of special importance: (1) those which belong to the relations of carbon and iron; and (2) those which contemplate molecular change in the iron itself. The first of these has been deliberately subordinated to the second," not from any want of abundant facts relating to it but because the author believes "that the possibility of molecular change in the iron itself, which results in its passage into a distinctive form of iron, is at present the more important subject for consideration, not merely in relation to iron, but as regards the wider question of allotropy in metals generally." Chemical elements act on each other in accordance with the law of Mendeléeff, and it may be that the relation between small quantities of elements and the mass of metal containing them may be in some way or other connected with the same law. It has already been proved in the case of gold, where the tenacity is the physical property affected.

In the case of iron it is difficult to say in what direction the law will show itself. "Possibly the direct connexion with the periodic law will be traced by the effect of a given element in retarding or promoting the passage of ordinary iron to an allotropic state; but the future of steel will depend on the care with which we investigate the nature of the influence exerted by various elements on iron, and the thermal treatment to which it may most suitably be subjected."—A. W.

#### *The Manufacture of Galvanised Iron.* B. Preu. Oesterr. Zeits. Berg. u. Hütten. **37**, 447.

THE zincing tanks are made of wrought iron  $\frac{5}{8}$  in.— $2\frac{1}{2}$  in. thick, they are heated from the sides, but only on the lower four-fifths of their height. Three processes are in use.

(1.) Winiwarter's. To guard against the formation of hard zinc (a ferri-ferrous zinc containing not more than 5 per cent. of iron), and the consequent brittleness of the plates, the tank is nearly filled with lead and covered with a layer of zinc about 1 in. thick, 2 or 3 per cent. of tin being added to the zinc to promote crystallisation. The plates are heated, cleaned, and dipped into a mixture of two parts of a solution of zinc chloride (50° B.) and three parts of a solution of ammonium chloride (5° B.), diluted with water to 8° or 9° B. The sides of the tank are protected from the corrosive action of the zinc by a refractory lining

extending just down to the level of the lead. The disadvantages are that the zinc must be continually renewed, and the surface always kept bright and free from oxide.

(2.) The most general method is to fill the bath with zinc only, and protect it from oxidation by a coat of ammonium chloride. The zinc adheres firmly to the finished plates, but the fumes are objectionable.

(3.) Küller's patented process merely consists in the removal of the superficial layer of zinc from the galvanised plates by means of steel wire brushes. There is no economy of metal, as the patentee claims, but the appearance is greatly improved, and the plates are more suitable for better class goods.—S. B. A. A.

#### *Roasting Zinc Blende.* W. Minor. Chem. Zeit. **13**, 1602—1603.

IN practice the time required for the elimination of sulphur from different varieties of blende varies from two to six hours. To determine the cause of this variation, the author roasted carefully selected samples of blende, and analysed them at intervals. The following results were obtained:—

(1.) Composition of the ores before roasting.

No. of Sample.	Zn Total.	Zn not combined with S or SiO <sub>2</sub> .	S.	Fe.
I.	37.81	6.65	21.05	2.33
II.	31.92	4.75	27.94	13.12
III.	49.29	5.83	22.11	2.06
IV.	32.76	5.03	30.24	15.98

(2.) Percentage of S after roasting.

No. of Sample.	One Hour.	Two Hours.	Three Hours.	Four Hours.	Five Hours.	Six Hours.
I.	10.32	2.83	1.80	1.71	0.95	0.08
II.	24.33	21.95	20.65	17.02	2.15	0.18
III.	14.69	6.27	1.23	0.22	0.16	0.16
IV.	27.25	24.30	18.25	11.94	4.27	0.04

The author infers that the elimination of sulphur is retarded to a much greater degree by iron pyrites than by even considerable quantities of zinc silicate.—S. B. A. A.

#### *The Refining of Silver and the Separation of the Bismuth contained in it.* C. Rössler. Berg. u. Hüttenm. Zeit. **48**, 387.

IN Rössler's method, which is chiefly employed for the refining of silver containing bismuth, at first the greater part of the lead and then the bismuth pass into the slag. The slag is ground up fine and fused with soda and charcoal. The metal thus obtained is granulated and boiled with strong sulphuric acid in a small iron kettle till completely converted into sulphate, excess of acid being avoided. On cooling the mixture is extracted in a wooden vessel, lined with lead, and of 250 litres capacity, with 200 litres of sulphuric acid of 20° B., the temperature not being allowed to exceed 10° C. At this low temperature the bismuth sulphate is dissolved (about 5 kilos. of bismuth in each charge). The solution is drawn off the insoluble lead sulphate, and the silver dissolved in it precipitated by metallic copper. The bismuth remaining in the solution is removed by heating the latter to 50° C.; the solution is then cooled and again used for dissolving. The lead, as well as the separated silver, contain bismuth, which is removed by digestion with hydrochloric acid. The solution is added to the washed bismuth sulphate, and the bismuth is then precipitated by metallic iron.—H. T. P.

*New Furnaces for Quicksilver in Spain.* Eng. and Min. J.  
1889, 430—431.

THE *Revista Minera* of Madrid gives the following description of two new continuous furnaces recently introduced by "El Porvenir" Company in Asturias for the treatment of its quicksilver and arsenical ore.

**Double Retort Furnace.**—The Figures 1, 2 and 3 of Plate I. indicate sufficiently its arrangement. The circumstance which gives novelty to this furnace is the fact of the discharge mouth being partially open for the entrance of air, which can be done without inconvenience or danger of escape of the fumes, owing to the artificial draft which is produced by a hydraulic ventilator similar, except as to size, to that for the shaft furnace. The retorts are of cast iron, and have a common hearth in which is burned small coal.

Every hour and a half, 50 kilos, of finely crushed ore are fed through the hopper. When the ore is very rich, it may be fed in small pieces, lime being mixed with the ore when it contains 15 per cent. of quicksilver. In this manner 1,600 kilos. of rich ore are treated in 24 hours.

For the condensation there are two larger chambers, other two smaller, a wooden compartment with water on the bottom, and afterward the ventilator and the tubing which carries the fumes to the chimney, in which no signs of quicksilver are to be seen.

From the first condensing chambers 90 per cent. of the quicksilver produced is recovered, and from the second nearly all of the remainder, for from the wooden compartment scarcely one kilo. of metal is produced after a year's work. A great part of the quicksilver runs out during the operation through small holes pierced in the chambers near the floor.

According to Rodriguez, the loss in this furnace does not amount to 1 per cent., and the cost of treatment of one ton of ore is 1 dol., which cost can be materially reduced if, in place of two, six retorts be placed in the furnace. The hearth consumes each 24 hours  $3\frac{1}{2}$  metrical hundredweights of fine coal, worth 37 cents. With this furnace not only is the treatment very perfect, but the great advantage of doing away with bricking the ore is gained, which costs more than 20 cents for each ton of ore.

**Stack Furnace.**—The form of this is slightly conical; it is 2 metres in diameter above the grate and 1·85 metres at the height of the throat, being terminated by a round arch, which has the charging hopper in its upper part. The height of the furnace may be considered as divided into two parts: the lower or hearth chamber being 2·85 metres and the upper portion 2·85 metres. See Plate II.

The hearth forms a chamber of less diameter than the rest of the furnace. At 85 cm. from the floor is situated the grate which is 1·10 metres in diameter, and with this dimension the walls continue vertically 80 cm. higher (Fig. 4a); above this a conical portion of 50 cm. which at the top has a diameter of 60 cm., then a cylinder 60 cm. high, covered by a round arch, pierced with holes, through which pass the products of combustion of the hearth. In order to give to this part of the furnace sufficient strength to support the weight of the ore, there are constructed over the grate, as is shown in Fig. 4a, two low arches, which sustain five courses of bricks, which in their turn support the upper portions of the furnace. The central opening O is protected by a cast-iron cap in such a way that the exit of the fumes can proceed without the admission of ore to the hearth. With this same object the other openings (a) below the central one have the angular section shown in Fig. 4a. The calcined ore is withdrawn through the doors P. The furnace chamber has externally a conical form, and is covered with iron.

All the interior of the furnace is constructed of fire-brick, of a thickness of 30 cm.; surrounding this lining there are four roony hollow spaces of 10 cm. in width and 80 cm. in length, which rise to the top of the body of the furnace and communicate below with the hearth at the level of the grate. A tower of ordinary material, 60 cm. thick, encloses the whole furnace. The throat is a pipe of cast iron 50 cm. in diameter and about 4 metres in length, placed with a slope toward the condensation chambers, where it branches off so as to communicate separately with the two series.

The condenser is composed of four chambers, each of some 10 metres capacity, placed two on the right and two on the

left of the pipe conducting the fumes from the furnace, each branch communicating with the upper part of the first on each side. The communication between the chambers is made through two little openings of rectangular section near the floor, sloping towards each of the sides of the chamber and into a conduit through which is running a stream of water. As is shown in Fig. 3a, the sooty precipitate, which formed, consisting almost exclusively of arsenious acid mixed with quicksilver, can be driven down immediately to the very foot of the chambers, where the quicksilver which is produced is run off through the channel *q* (Fig. 1a) to the receptacles for it. These chambers communicate by means of sloping iron pipes with four other smaller ones of similar construction, and placed in line at a higher level. The chimney, placed at 100 metres distance, is constructed so as to take advantage of steep ground, and its mouth is partially closed with loose bricks, over which coke is spread to the thickness of 30 cm., a very simple arrangement, which diminishes the smoke to such an extent that from a distance the furnace does not seem to be working.

This furnace calcines  $8\frac{1}{2}$  tons of ore in 24 hours in pieces from 800 to 600 cc. and larger. The charges are fed every 75 minutes, each charge weighing 443 kilos., coke amounting to 42½ kilos. in 24 hours being mixed with the ore. The calcination is very good, the ore when discharged not containing more than 0·01 to 0·02 per cent. of quicksilver.

—O. H.

For Plates I. and II. see pages 78 and 79.

## PATENTS.

*Improvements in or connected with the Coating of certain Metals with other Metals or Alloys.* W. Charnock, Warrington. Eng. Pat. 17,476, November 30, 1888. 6d.

In coating iron and steel with zinc tin or terne, an alloy harder and less fusible than the coating metal itself, and of less value, as a covering agent, collects at the bottom of the tank in which the process is conducted. The patentee subjects the articles to be coated to a bath of this hard alloy in a separate tank and finishes them in one of the pure metal, thus effecting a saving in the latter.—B. B.

*Manufacture or Production of Metallic Alloys.* P. M. Parsons, Blackheath. Eng. Pat. 187, January 4, 1889. 4d.

ONE HUNDRED parts by weight of iron, 50—105 of tin, 5—40 of manganese, 3—50 of aluminium, are melted together and cast into ingots. The mixture is used for adding to copper, brass, gun-metal, or bronze in the proportion of 1—5 parts by weight for every 100 of the copper or copper alloy. For adding to bronze or gun-metal the quantity of tin mentioned above may be increased, but should be kept within the limits there defined for brass or yellow metal. Similarly a larger quantity of manganese (which may be used as rich ferro-manganese) may be added to the former than to the latter. The function of the aluminium is to lessen the corrodibility, increase the fluidity, and raise the strength of the product. —B. B.

*A New Fluxing or Protecting Material for Use in the Welding, Brazing, and Coating of Metals.* P. P. Craven, Forest Gate. Eng. Pat. 15,887, October 9, 1889. 4d.

A SUBSTANCE found near Port Augusta, S. Australia, as yet unnamed, and having an average composition of "oxide of iron" 2·90, alumina 4·78, calcium carbonate 0·95, potash 0·15, soda 0·21, magnesia 0·35, lead sulphide 0·12, water 0·58, silica 89·69 parts per cent. respectively, is used by the patentee as a brazing and welding flux, and as a covering for a bath of one metal (e.g. copper) with which another (e.g. iron) is to be coated. By its means he claims to be able "to weld iron to iron, copper to copper, steel to steel (even cast steel to cast steel), or any one of these metals to either of the others with great facility."—B. B.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

*The Electrolysis of Sodium Chloride Solution with Direct Production of Chlorine and Crystallised Soda.* W. Hempel. Ber. 22, 2475—2478.

See under VII., page 65.

*Electrolytic Separation of Cadmium from Copper.* Smith and Frankel. J. Franklin Inst. 1889.

See under XXIII., page 108.

*Action of an Electric Current on Sulphocyanides.* Smith and Frankel. J. Franklin Inst. August 1889.

It is found that when an excess of potassium sulphocyanide is present in a solution of nitrate or sulphate of manganese a greyish white compact deposit of metallic manganese is obtained at the cathode when a feeble current is used. Without the sulphocyanide oxide of manganese is produced at the anode. Nickel, cobalt, iron, and several other metals separate easily from cold sulphocyanide solutions when a weak current is used.—W. W. H. G.

### PATENTS.

*An Improved Galvanic Cell or Battery for Electric Lighting or for other Purposes.* S. Miller, London. Eng. Pat. 14,322, October 5, 1888. 8d.

THE outer cell is lined with carbon, corrugated on its inner surface. A porous pot, inside this, is preferably divided into two compartments, a larger and a smaller, the former containing water and a zinc rod, the latter acid to acidulate the water by diffusion through the partition. The depolarising solution preferred is described in Eng. Pat. 14,323 (following abstract). Supply, overflow, and discharge pipes may be provided if desired.—E. T.

*An Improved Electrolyte or Depolarising Solution for Galvanic Batteries.* S. Miller, London. Eng. Pat. 14,323, October 5, 1888. 4d.

A SOLUTION is made up in the following proportions, which may, however, be slightly varied. To water, 40 oz., add sulphuric or hydrochloric acids, or a mixture of the two, 20 oz.; then sodium nitrate, 6 oz., potassium bichromate, 1½ oz., both finely powdered; lastly, sodium chloride, 1 oz. Proportions and methods of preparation may be slightly varied.—E. T.

*Improved Method of and Apparatus for the Formation of Organic Oxides and the Oxidation of Matter Suspended or Dissolved in Liquids.* J. G. Lorrain, London. Eng. Pat. 16,093, November 7, 1888. 6d.

See under XVIII. B., page 97.

*Improvements in Storage or Secondary Batteries.* H. H. Lake, London. From H. Walter, Cincinnati, U.S.A. Eng. Pat. 16,479, November 13, 1888. 8d.

THE electrodes are formed of carbon or of some base metal coated with one of the noble metals, such as gold or platinum, the electrodes being surrounded by closely-packed granulated carbon, kept in position either by bags of indestructible material or by insulating partitions. The solution employed consists of acetate of lead dissolved in vinegar, to which some red lead is added.—B. T.

*Improvements in the Manufacture of Cyanogen Compounds from Sulpho-cyanides.* T. Parker and A. E. Robinson, Wolverhampton. Eng. Pat. 17,447, Nov. 30, 1888. 4d.

See under VII., page 67.

*An Improved Separator for the Plates of Primary and Secondary Galvanic Batteries.* J. Mosceley, Manchester. Eng. Pat. 17,642, December 4, 1888. 6d.

A STRIP of vulcanite, celluloid or similar material, of a width greater than its length, has a shape given to it, such as might be obtained by the following operations:—It is first bent over the plate at its middle, so that the two halves or limbs lie with their width parallel to the faces of the plate. Each limb is then twisted round its own axis to 90° from its former position, so as to bring the width of the limb perpendicular to the surface of the plate. In practice, the above shape may be given by moulding or by bending while hot.—E. T.

*Improvements in Voltaic Batteries.* H. J. Harris and J. Garford, London. Eng. Pat. 17,694, December 4, 1888. 11d.

THE carbon plates are formed with a stud to them, this stud passing through the bottom of the cell to serve as a contact piece. Separated from the carbon chamber by a porous partition is the zinc chamber, the end of the zinc also passing through the bottom of the cell. These studs are then connected up as desired with suitable metal conductors, and they are buried in a non-conducting cement, which will withstand the action of the fluids used in the battery. A cam-shaped moveable handle at the top is arranged for jamming the lid hard down, and also for ease of transport. A solution of sulphuric acid, nitrate of soda, and bichromate of soda in water is used in the carbon cells, and water slightly acidulated with sulphuric acid in the zinc cells.—B. T.

*Improvements relating to Secondary Batteries.* J. L. Huber, Hamburg, Germany. Eng. Pat. 18,589, December 19, 1888. 8d.

A NETWORK, grating, or screen of suitable material is embedded in the active mass of the plate, and perforations are made in the active mass to allow of circulation of the electrolyte, and also to give greater surface to the plate.—B. T.

*Improvements in Electrical Accumulators.* J. C. and G. Fuller, London. Eng. Pat. 18,636, December 20, 1888. 4d.

THE plates are separated by porous partitions or porous pots.—E. T.

*New or Improved Apparatus for enabling Temperatures to be Ascertained at a Distance.* J. G. Lorrain, London. Eng. Pat. 18,752, December 22, 1888. 8d.

AT the station whose temperature is to be measured a high resistance wire or coil of wire of suitable material dips into a tube, in the lower portion of which is mercury or other suitable fluid. Wires lead from the two ends of the coil to the measuring station, where the resistance of the coil can be taken at any time. As the temperature at the first station rises, the level of the fluid in the tube rises, thus diminishing the resistance measured at the second station, and so enabling the temperature of the first place to be ascertained at any moment. Various appliances are described for use at the first station.—B. T.

*An Oblique-Meshed Grid Plate for Storage Batteries.* T. W. Bush, Brosceley. Eng. Pat. 18,978, December 29, 1888. 4d.

EACH perforation consists of a hole passing obliquely downwards (by preference) from each face of the plate into its substance, and either joining in the middle with its fellow from the other side, or being separated from it by a thin partition.—E. T.

*An Improved Plate for Electrical Storage Batteries.* M. Doubleday, Nottingham. Eng. Pat. 18,981, December 29, 1888. 4d.

GRIDS are used constructed with any number of larger holes on one face, and a greater number of smaller holes on the other face, so arranged that one or more of the smaller holes opens into each of the larger ones. Two of these grids are then fastened together to form each plate, the larger holes being brought face to face so that a number of chambers are formed inside, with small openings to the two outer faces.—B. T.

*Improvements in Electric Batteries.* J. Y. Johnson, London. From F. Gendron, Paris, France. Eng. Pat. 19,058, December 31, 1888. 8d.

A POROUS pot is employed which resembles those used in Grove cells, except that, instead of going straight across the cell, it pursues a deeply zig-zagged course. The outer cell has its walls lined with carbon, with leaves of carbon passing from the walls into each bend of the zig-zag. Inside the porous cell, in each bend, is a zinc plate made up of several thicknesses of thin zinc held in a framing of conducting material. A small compartment communicates with the outer chamber by a hole near the bottom of the latter. Into this compartment the spent liquor flows as fresh liquor is admitted, and passes off by an overflow pipe. The porous pot is provided with an arrangement on the same principle.—E. T.

*Improvements in Nickel Plating Engraved Rollers.* J. Parkinson, Lancaster. Eng. Pat. 702, January 14, 1889. 8d.

THE rollers are continuously or intermittently "scratch-brushed" in the nickel-plating baths themselves. Mechanism is described for carrying this into effect automatically. The rollers may be transferred from one bath to another, wrapped in india-rubber cloth or such material. The roller itself is kept in continuous rotation against a "scratcher," consisting of an elongated brush, to which a reciprocating motion is given; or of a belt with bristles on the inside, kept stationary while the roller revolves against it; or of a scratch-brush of the usual shape, kept revolving, and slowly travelling from end to end of the roller.—E. T.

*Improved Process of Treating Plates and the like for Facilitating the Removal of Galeano-plastic Deposits contained thereon.* A. J. Boult, London. From A. R. Reinfeld, Vienna, Austria. Eng. Pat. 3222, February 22, 1889. 6d.

TO facilitate the removal of galvano-plastic deposits, the metal on which the deposit is to be made is coated with a thin covering of nickel, and this nickel is then either oxidised or treated with some soapy or fatty substance to make it smooth. Very thin foils of deposited metal can then easily be removed from this surface.—B. T.

*Improvements in connection with Electric Fuses.* W. H. Scott and Lawrence, Paris, and Scott, Norwich. Eng. Pat. 6332, April 13, 1889. 6d.

INSTEAD of ordinary lead or tin fuse wire, a fine wire of high conductivity such as copper or silver is employed, and is enclosed in small glass tubes with suitable contact pieces at the end for fitting into the fuse holders.—B. T.

*Improvements in Signalling Apparatus for Indicating the Presence of Explosive Gases in the Atmosphere.* E. Stern and M. Kaufmann, Cologne, Prussia. Eng. Pat. 13,668, August 30, 1889. 6d.

A DEEPLY corrugated tube of thin metal, closed at the top, has its open end closed by a porous diaphragm or membrane. If brought into the neighbourhood of light gases, these diffuse through more rapidly than the heavier gas inside can diffuse out. The pressure rises therefore, and the tube by becoming elongated, makes an electric contact with a point fixed above it, and so gives warning by ringing an electric bell.—E. T.

*Apparatus for Automatically Charging Secondary Batteries or Accumulators.* S. C. C. Currie, Philadelphia, U.S.A. Eng. Pat. 13,864, September 3, 1889. 8d.

WHEN the battery has been sufficiently charged, spray is given off, which settling on two metal pieces, placed close together in the top of one of the cells, makes contact between them and so completes a circuit through an electro-magnet and a signal bell. The armature of the magnet is at once attracted, and breaks circuit between two contact pieces, so disconnecting the charging dynamo from the cells. Immediately afterwards, the armature establishes a contact through a second circuit, containing a resistance coil, so that a continuous small current passes round the same electro-magnet, and enables it just to hold up its armature in position. If, however, the E.M.F. of the cells fall owing to the approach of complete discharge, the magnet becomes too weak to retain its armature, which drops and re-establishes the charging circuit. If a short circuit should have occurred in one of the cells, the E.M.F. of the whole battery will be too small to enable the armature to be retained, and it will consequently continue to vibrate up and down, the signal bell ringing at the same time till attention has been attracted.—E. T.

*Improved Electrodes for Secondary Batteries.* G. E. Heye, Charlottenburg, Germany. Eng. Pat. 15,383, October 1, 1889. 4d.

IN the construction of accumulator plates metals should be used which have a "high powder of oxidising," and for this reason the inventor uses plates of alloys of chromium, manganese, wolfram, and lead, and also plates of oxides of chromium and wolfram.—B. T.

*Improvements in the Method of and Apparatus for "Forming" or Charging Plates for Electrical Accumulators.* S. C. C. Currie, Philadelphia, U.S.A. Eng. Pat. 15,446, October 1, 1889. 8d.

IN order to make a strong, compact plate, and therefore one which is but little liable to expansion, the active material, in the form of a plate surrounded by a rim or bead, is held in a strong frame, and wedged up by keys against the sides and ends of the containing cell, so that its expansive efforts during formation are exerted upon itself. Suitable perforated and corrugated plates of insulating material are inserted between the positive and negative plates, and the connexions are so arranged that each plate can be conveniently withdrawn at any time.—B. T.

*Improved Methods of Producing Aluminium and its Alloys by Means of Electricity.* L. Q. Brin, Paris, France, and A. Brin, London. Eng. Pat. 15,508, October 29, 1889. 6d.

THIS is an extension of the methods mentioned in Eng. Pats. 3547, 3548, 3549, 8746, and 8747 of 1888 (this Journal, 1889, 199, 399, and 548). The flux used consists of bauxite 100 parts, salt 125, borax 25, and these are fused in a furnace so constructed that an inert gas can be introduced when required, to carry the metallic vapours to any desired chamber, or to bring them into contact with the metal with which it is desired to make an alloy. Two methods of using the electric current for the reduction of aluminium from the

fused flux are described, one in which potentials of from 50 to 100 volts are used, and an arc is formed at the surface of the fused mass, and another, in which potentials of from 2 volts upwards are used, the fused mass being used as an electrolyte. In the first case the arc acts partly by increasing the temperature and partly electrolytically; in the second method an alloy of sodium and aluminium is formed, and falls to the bottom of the crucible as a button.—B. T.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

*The French Stearin Industry, and this Section of the Paris Exhibition.* B. Lach. Chem. Zeit. **13**, 1157, 1218—1219, 1335—1336, 1374.

THE author, in a series of articles, gives an account of this industry and its exhibits. Great studies have been made in stearin production in France during the last 10 years.

The Exhibition shows this not only to be so with regard to products, but to machinery and apparatus, of which multifarious forms are to be seen, and the sight of which must give an impulse to the industry in other countries. The French, he admits, entirely surpass his own countrymen in this branch. The machinery exhibit of J. Morane, Jeune, alone, which is first described, he estimates as worth about one million francs.

*Saponification.*—The autoclave machines are of two kinds, those for lime saponification and those for saponification by means of high-pressure steam alone.

Of the latter, three systems are described.

1. That of G. Levy (the inner construction of which is very complicated) is of sheet copper 30 mm. thick. Opinions of it differ. The work is very good.

2. Thermo-dynamical system of L. Hugues, from the stearin works of L'Etoile, Paris. This was seen in operation by the author. The saponification takes seven to eight hours, and the yield of glycerin, of 28° B., is 9 to 10 per cent. The tallow fatty acids are as clear as palm oil. The fatty acids can be directly distilled with production of 50 per cent. of stearin, m.p. 53°. By careful previous treatment with sulphuric acid, a further yield of 8 to 10 per cent. of stearin can be obtained.

3. A. Michel's apparatus, copper 33 mm. thick. It is brought directly in contact with the fire. See Fig. 1, where

Fig. 1.

*a, a*, are the autoclaves, which being fired, the water *b, b*, is converted into steam, which forces the fatty acids through *c, c*, into *d*, where they are returned, through *h, h*, to *a, a*, and thus kept in intimate mixture.

*Lime saponification.*—

4. System of L. Droux. Spherical, with stirring apparatus.

5. System of J. and B., not exhibited, but seen at work by the writer.

6. That of Morane, Ainc, also with mechanical stirrer.

*Glycerin.*—For the treatment of crude glycerin several processes are in use, mostly by use of exhaust steam.

*Distillation.*—Most attention is paid to this form of apparatus in France, which is also shown to advantage by the firm of J. Morane, Jeune.

The condensing apparatus is good, no smell being observable in even the large Paris works, where 8,000 kilos. of fatty acid per 24 hours were distilled. Three forms are described, viz., those of Michl, Lewy, and Marix.

A simple effective flange, Fig. 2, is shown, which on being screwed up forms a perfectly tight joint.

Fig. 2.

Michel's apparatus is of copper. Lewy's is constructed of cast iron. It is shown in Fig. 3; *c* is the fire, at *d* steam

Fig. 3.

is admitted, which after being superheated in *a*, passes through *b*, and thence is distributed by the T-pipe *f*<sup>1</sup>. The fatty acids are heated so far by entering through the spiral *i*.

The author, however, prefers the arrangement of Marix, of the form used in petroleum refineries, in which the distillation takes place at a lower temperature, as low as 250° to 255° where an air-pump is used. Its capacity is 1,500 kilos. and can distil 4,000 to 5,000 per 24 hours. The loss in tar is only  $\frac{1}{4}$  to  $\frac{1}{2}$  per cent. The fatty acids are very white, colourless, and crystalline, they press well, giving 50 to 60 per cent. of homogeneous stearin, melting at 53° to 54°. The principal advantage is the low temperature, 250°—300°. The price, 13,500 francs, is very cheap. It can be worked without the air-pump, and will distil (in still of 1,600 kilos. capacity) 8,000 kilos. per 24 hours. The tar is about 4 per cent., and a good yield of 53° stearin is obtained.

The fatty acids are in thicker cakes than used in Italy, Austria, or Germany. Morane, Jenne, has a simple form of press which is easily manipulated, and requires few fittings and little space.

*Tar.*—Many works distil to thin consistency and treat with English sulphuric acid 66° B. and distil to dryness.

Other works distil to elastic consistency and redistil the last fraction.

*Pumps and Presses.*—Many varieties of pumps are shown. Of hydraulic presses the newest types of hot or cold are all horizontal. The main feature is that these presses are double. The press cylinder *a*, Fig. 4, is in

Fig. 4.

the middle of the press. In working, the piston carries the moveable wrought-iron plate *l* against the fixed end *b*, while the drawing rod *f* (fixed to both presses) presses the moveable plate *c* against the fixed end *g*. The press cylinder is of cast steel and is supported at *s*. The pistons are of strong brass. The presses are constructed for 30, 50, or more cakes. The heating arrangement, which is good, equable, and exceptionally durable, is shown, Fig. 5.

Fig. 5.

Screws are at *a, a*, lead plugs at *b, b*. In Fig. 4 a smaller cylinder *i* will be seen; this is for use in opening of press, which it pushes back when required by turning a three-way valve and opening the return water valve at the large cylinder.

The cold presses are similar. In Fig. 6 is the method of fixing the bags, *a* being plates and *b* bag.

Fig. 6.

The author concludes his notice of the exhibit of Morane, Jenne, with some remarks on an ingenious but complicated triple press, and a few notes as to candle machines.—D. A. S.

*On Wax Investigation.* H. Röttger. Chem. Zeit. **13**, 1375.

G. BUCHNER (Chem. Zeit. **12**, 1276, this Journal, 1888, 871) found with what he termed "absolutely pure" beeswax considerable difference between the acid ether and saponification equivalents of yellow, air-bleached, and chemically-bleached wax. This is not in accordance with results of other investigators such as Helfenberg or Allen, who do not find much difference. The author's experiments confirm these latter results, and he accordingly questions the purity of Buchner's samples.—D. A. S.

*Solidifying Points of Viscous Oils.* Holde. Mitt. König. tech. Versuchs. **1889**, **3**, 119—126.

See under XXIII., page 112.

*Process for the Saponification of Fats.* J. Kaster. Les Corps gras, ind. **1889**, **16**, 148.

THE fat is subjected to the joint action of zinc chloride (4—6 per cent.) and superheated steam (at 200°—220° C.). —B. B.

### XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

#### PATENTS.

*Improvements in Lacquers and Varnishes.* S. Challows, London. Eng. Pat. 16,035, November 6, 1888. 4d.

CRUDE or refined camphor oil is used in addition to, or instead of, the solvents ordinarily employed.—E. G. C.

*An Improved Apparatus for Dressing White Lead and other Colours.* A. J. Smith, Battersea. Eng. Pat. 16,185, November 8, 1888. 8d.

This apparatus consists essentially of a slightly inclined cylinder, composed of a series of ribs or bars, over which silk or some other textile material is stretched. The ends of the cylinder are left open, so that the stream of colour can be led through the apparatus, the finer particles passing through the textile fabric, while the coarser portions are discharged into a tank.—E. G. C.

*A Cleaning and Polishing Powder for Metals.* J. E. Storer, Sheffield. Eng. Pat. 17,291, November 28, 1888. 4d.

A mixture of lime (140 parts) with rouge (1 part). —E. G. C.

*An Improved Anti-Corrosive Composition for Protecting Iron Vessels or the like.* W. P. Thompson, Liverpool. From P. Leonardi and P. Zen, Venice, Italy. Eng. Pat. 13,345, August 24, 1889. 4d.

The varnish is applied in two coats, the first consisting of a solution of tar in essence of turpentine or benzene, with the addition of 10 per cent. of oxide of iron. The second coat is composed of 10 per cent. of ammoniacal chloride of mercury, 10 per cent. of white arsenic or metallic arsenic, 20–30 per cent. of oxide of iron, “the whole mixed with 100 parts of the above-described solution of tar and turpentine or other varnish.”—E. G. C.

### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

*The Introduction of Hydrogen Peroxide in Tanning.* C. F. Gohring, Gerber Zeit. 1889, 44.

COW-HIDES are often obtained spotted or of too dark a colour. If such leather be washed with a solution of neutral Marseilles soap, and then at once painted with a solution of hydrogen peroxide which has been neutralised with ammonia, and be then dried by gentle warmth or exposure to a current of air, the objectionable colouring matter will be permanently removed without injury to the leather. The author recommends the use of hydrogen peroxide to disinfect hides which have been long stored, and also to preserve extracts of tanning materials.—H. T. P.

*Application of Pine Bark to Tanning.* A. Frank. Ber. des Ver. z. Förder. d. Gewerbe. 1889, 171.

THE author draws attention to the fact that in the manufacture of cellulose from pine wood the bark is entirely wasted. He has established that this refuse has a value for tanning purposes, which would effect an economy of a shilling a hundredweight on the cellulose.

Leather treated with pine bark alone is inferior in quality, colour, and weight, to that prepared with oak bark, but the author quotes Eitner to prove that the extract of pine bark would form a perfect complement to certain imperfect tanning materials such as chestnut wood, quebracho, &c.

—S. B. A. A.

*Benzoyl tannin.* C. Bottinger. Ber. 22, 2706–2709.

By the action of benzoyl chloride upon the aqueous solution of tannin, made strongly alkaline with sodium hydrate (Baumann, Ber. 19, 3218), a benzoyl derivative of characteristic properties is obtained. It is freed from the by-products of the reaction by exhaustive treatment with ether, and is obtained as a semi-crystalline yellowish powder. It softens to a glutinous mass on boiling with water, but does not dissolve; it is not sensibly attacked by water at 165°. It dissolves in sulphuric acid on gently warming. On diluting the solution the original molecule is found to be completely resolved into gallic and benzoic acids. Benzoyl tannin dissolves in phenylhydrazine on warming; the product of the reaction is resolved on treatment with boiling ether into two bodies: (a) crystallising in long colourless needles; (b) bright yellow coloured and amorphous.

The author has commenced a methodical comparison of the benzoyl derivatives of “tannins” from various sources, more particularly in relation to their reactions with phenylhydrazine.

The molecule of quercitanic acid is characterised by the presence of a ketone group, contained in a carbohydrate residue, probably allied to levulose (Ann. 238, 366), and easily split off.—C. F. C.

#### PATENTS.

*Improvements in Machinery or Tumblers for Treating Hides, Skins, and Leather.* P. A. Jesson, Paris, France. Eng. Pat. 17,782, December 5, 1888. 8d.

THE tumblers are formed by taking two hollow pyramids of metal or other suitable material, and arranging them base to base on a common axis. The pyramids may be either equal or unequal in size, and may have any convenient number of sides, and may be attached directly to each other at their bases, or may be separated by a polygonal casing of any desired width. One of the tumblers is hollow, and serves for the introduction of water or other liquid during the rotation of the machine. A door is provided for charging or emptying the tumbler.—B. H.

*Improvements in Extracts applicable for Use in Fermenting and in the Preparation of Leather.* M. P. Hatschek, London. Eng. Pat. 18,399, December 17, 1888. 4d.

THIS invention is an addition to Eng. Pat. 3363 of 1888 (this Journal, 1888, 859). The extract called “Maltopeptine” which forms the subject of the former patent can be used to replace egg-yolk, animal brains or other albuminous matter for fermenting kips, skins, and hides and for dressing them, producing “the same or very similar and frequently better results” than the aforesaid substances. The maltopeptine can be used as a dressing for leather after mixing with oil. The peptonising of the raw material used can also be accomplished by using the juice or tissue of the agave.—B. H.

*Improvements in Machinery or Apparatus for the Treatment of Hides and Skins.* H. E. Freudenberg, Weinheim, Germany. Eng. Pat. 645, January 12, 1889. 8d.

THIS invention is for apparatus for the softening, stretching, fleshing, and cleansing of hides and skins. According to this invention knives for fleshing are dispensed with and replaced by a rotating grinding stone, against which the flesh sides of the hides are pressed under an abundant and continuous water jet. The periphery or face of the grindstone is formed with deep narrow grooves diverging from the centre, which answer the purpose of the angular position of the fleshing knife as held by the workman. Drawings are given, and for further particulars the specification must be consulted.—B. H.

*Improvements in the Process for Freeing Kips, Skins, and Hides from Lime, and for Causing the same to Swell.* J. Hauff, Fuerbach, Germany. Eng. Pat. 12,521, August 7, 1889. 4d.

As cresotinic acid has been found to have too powerful an action on light skins, oxynaphthoic acids (hydroxynaphthoic acids), by which should be understood the carbon-containing acids formed by the action of carbonic acid on the alkaline compounds of  $\alpha$ - and  $\beta$ -naphthols, have been tried and found suitable. It has been found also that mixtures of salicylic acid and cresotinic acid, of salicylic acid and oxynaphthoic acid, of cresotinic acid and oxynaphthoic acid, or of all three, are suitable for heavy skins. It has also been found that a less quantity of these acids is required for the removal of lime from the skins or hides than corresponds to the neutralisation of the lime. This is explained by the property possessed by these acids of forming soluble basic lime salts.—B. II.

*Improvements in and relating to a New and Useful Process of Chrome-Tanning Leather, and in and to the Article produced thereby.* P. Jensen, London. From D. Pierson, Wilmington, Del., U.S.A. Eng. Pat. 13,126, August 20, 1889. 6d.

By this process tanned leather and skins are made permanently soft and flexible without the aid of oils or grease. The "chemical preparation" used is prepared as follows:—Chromic hydrate is prepared by precipitating a solution of chrome alum with carbonate of soda. The chromic hydrate so obtained is dissolved in sulphuric acid of 16°–18° B., and reprecipitated. A vat is provided of suitable size, and of a depth exceeding by 2 ft. the length of the hides, and filled with water. Sulphuric, nitric or other suitable acid is then added till the liquor is of a gravity of 4° B. When cold, excess of the pure chromic hydrate is added, and the solution agitated till all the acid is neutralised. The hides are then suspended vertically in the liquor for from 12 to 18 hours. The hides are then removed and subjected to the action of a warm solution of logwood. The contents of the vat are agitated as before, and are then ready for another lot of hides. This is repeated until the chromic hydrate is entirely consumed.—B. II.

*Improved Means and Process for Preparing Skins and Hides for Tanning.* R. C. Want, London. From G. Mitchell and R. W. Rutherford, both of Dunedin, New Zealand. Eng. Pat. 13,542, August 27, 1889. 4d.

This invention is for the employment of an aqueous solution of sulphate of ammonia, or of sulphate of soda, or of sulphate of magnesium, or of sulphate of potassium for "bating" or "paring" hides preparatory to tanning. The hides are steeped in the solution in the ordinary manner, and are then "scudded" and washed. The strength of the solution is regulated according to the thickness of the hides to be treated, and the time to be allowed, and there is no difference in the treatment of hides and of skins. The solution of sulphate of ammonia is believed to be the best for the process.—B. II.

*An Improved Method of preparing Hides for Tanning.* A. Hull, New Winstead, Conn., U.S.A. Eng. Pat. 14,595, September 17, 1889. 4d.

This invention relates to the "bating" of hides, i.e., their treatment after unhairing and before tanning.

The "bate" is made by dissolving about 4 oz. of crystallised gallic acid in about 10,000 lb. of water. In this solution the hides, after washing to remove as much as possible of the lime, may be immersed for from 10 to 24 hours. The inventor states that after this treatment the hides are soft and flaccid, and by working on the beam the neutralised lime and any extraneous matter will be readily worked out, and the hides rendered in proper condition to be tanned in the usual manner.—B. II.

## XV.—AGRICULTURE, MANURES, Etc.

*Relation between the Colour of Plants and the Richness of the Soil in Fertilising Ingredients.* G. Ville. Compt. Rend. 109, 397–400.

The author's mode of analysing soils by growing the same crop in a number of measured experimental plots arranged as below, has been carried out by him year after year at Vincennes and elsewhere, the following table showing the results obtained at the station named:—

Plot.		Yield of Wheat per Hectare.	
		Total Harvest.	Grain.
1	Complete manure.....	Kilos. 9,579	Hectolitres. 39
2	Same manure without nitrogen ..	4,317	13
3	" " " phosphate.	7,533	24
4	" " " potash ....	7,524	28
5	" " " lime .....	8,290	37
6	No manure .....	3,542	11

These figures plainly indicate that the soil is most deficient in available nitrogen, well provided with lime, not so well with potash, and still less with phosphoric acid. For a number of years the author has observed that the colour of the crops on the different soils furnishes much the same indications as the weighing of the harvest, and, as an example, he gives specimens of the tints, with numerical values attached, afforded by a series of plots of hemp. The observations have been made in three ways: (1) By direct comparison, looking through blackened tubes, of the colour of the crops, with that of skeins of green worsted, selected according to the scale of colours in use at the Gobelin factories. (2) By drying equal weights of the leaves in vacuo, extracting with the same quantity of alcohol, and observing the tint in a colorimeter. (3) The last process is best carried out by first removing the yellow colouring matter (the crystallisable carotene of Arnaud) from the dried leaves by extraction with petroleum ether. The residue from this extraction yields a pure green tint to alcohol, but if the extract in petroleum ether be evaporated in vacuo and taken up with carbon disulphide, it furnishes another term of comparison, since the yellow colour is found to vary in tint, *pari passu*, with the green. The following are the figures attached to the coloured spaces illustrating the paper:—

Manure.	Colour of Plants viewed directly.*		Colorimeter Value of	
	Green.	Yellow.	Green Extract (in Alcohol).	Yellow Extract (in Carbon Disulphide).
Stimulating (100 kilos. N).....	9	15	100	100
Complete (75 kilos. N).....	9	14	74	90
Without nitrogen...	5	7	38	57
Without phosphate.	9	13	71	80
Without potash.....	5	10	66	72
Without lime .....	5	12	72	90
No manure .....	5	11	53	71

\* These numbers correspond with the scale of the Gobelin laboratory.

The author suggests the possibility of determining, by simple colour measurement of the crop and comparison with standard colours, the requirements of the soil as regards manure.—J. M. H. M.

*Fixation of Atmospheric Nitrogen.* Berthelot. *Compt. Rend.* **109**, 417—419.

THE author briefly reviews the controversy, and claims that Ville's early conclusions, as well as his own experiments of some years past, have been completely borne out by the results of Dehérain, Joulie, Hellriegel, Wilfarth, Breal, Frank, and Tacke. Admitting again that Schläsing's negative results as to the fixation of nitrogen by soil alone are due to such causes as the deleterious action of mercury vapour, overheating, or a too confined atmosphere on the microbes essential to the fixation, or else to experimenting on soils already surcharged with nitrogen by the growth of leguminous plants, the author announces a new research on the volatile nitrogenous bodies exhaled by plants and soil into the air.—J. M. H. M.

*Formation of Ammonia and Volatile Nitrogenous Compounds at the Expense of Plants and Vegetable Soil.* Berthelot. *Compt. Rend.* **109**, 419—423.

It has long been known that plants grow badly in a confined atmosphere saturated with aqueous vapour, and this fact was forced on the author's attention in those of his experiments on the fixation of nitrogen by soils and plants in which the pot of soil, or soil and plant, was placed on a large glass dish and covered with a bell jar. Better results were obtained by passing two or three times the volume of air contained in the bell jar through the apparatus once a day, but even then the growth was much inferior to that of plants grown in free air. Thinking it possible that the plants or soil exhaled small quantities of noxious compounds, the author collected with the greatest care the condensed water which ran down the sides of the jar and collected in the glass dish, and maintaining a slightly acid reaction by the cautious addition of sulphuric acid from time to time, submitted the whole quantity to examination at the close of the experiment. No particle of soil was suffered to come into contact with this condensed water, which remained perfectly limpid, and grew no moulds. The ammonia in it was determined by distillation with magnesia, and the organic nitrogen by evaporating down the neutralised and filtered residue and making a soda lime combustion. Two specimens of the results obtained are subjoined:—Pot No. 78: 2·139 kilos. of soil containing 1·702 grms. of nitrogen per kilo.; water 0·214 kilo. Duration of experiment, May 18 to June 13. Capacity of bell jar 50 litres. Nitrogen fixed, 2·8 per cent. of the initial nitrogen. The water of condensation contained ammonia 0·0012 grm., and organic nitrogen 0·0009 grm. Pot No. 76: 3·112 kilos. of the same soil with 0·311 kilo. of water. Sown with vetches. Duration of experiment, May 18 to June 10. Nitrogen fixed by plant and soil = 7·0 per cent of the initial nitrogen. 150 litres of air were passed through the bell jar each day, and one litre of CO<sub>2</sub> added. The water of condensation contained ammoniacal nitrogen 0·0000 grm., organic nitrogen 0·0007 grm. In another experiment, in which the plants grew badly, 0·0015 grm. ammoniacal nitrogen and 0·0012 grm. organic nitrogen were obtained, and in another, where the plants were still worse, and finally became mildewed, 0·0076 grm. ammoniacal nitrogen and 0·0051 of organic nitrogen were obtained. Small though these quantities are, they furnish some support to the idea that poisonous nitrogenous compounds, possibly analogous to the ptomaines exhaled from animals, are given off into the air by plants or soil.—J. M. H. M.

*Nitrification of Ammonia.* T. Schläsing. *Compt. Rend.* **109**, 423—428.

THE experiments described in this paper were made to ascertain whether during the nitrification of ammonia any of its nitrogen is given off in the free state. Soil mixed with a known weight of ammonium salt was introduced into an air-tight apparatus, together with an accurately measured volume of air, and as soon as nitrification set in oxygen

was supplied at intervals; the nitrogen at the end of the experiment was measured and compared with that at the commencement. The figures of one experiment will serve as a type of all. Two hundred grms. of moist earth containing 1·1 mgrms. of ammonia were mixed with 0·539 grm. of ammonium sulphate containing 138·8 mgrms. of ammonia. The ammonia lost by volatilisation from the mixture during the experiment was recovered and measured; it amounted to 1·8 mgrms. Therefore the nett ammonia to be nitrified was 138·1 mgrms. = 113·8 mgrms. of nitrogen. The experiment was started on March 20th, and from the 22nd to the 30th oxygen was supplied at intervals; the experiment ceased on April 9th. During the nitrification 552 mgrms. of oxygen disappeared and the nitrogen increased by 0·65 mgrm. 112·3 mgrms. of ammoniacal nitrogen disappeared and were replaced by 109·7 mgrms. of nitric nitrogen. Thus, of the 2·6 mgrms. of ammoniacal nitrogen which disappeared without being nitrified, only 0·65 mgrm. could have been evolved as free N, even supposing this, and not experimental error, to be the source of the extra 0·65 mgrm. of free nitrogen. Probably the balance went to support the nitrifying organism. Of the oxygen used, nine-tenths were recovered in the nitrate formed, so that in presence of ammonia to be nitrified the nitrifying organism seems to provoke but a very slight oxidation of the carbon and hydrogen of the soil. In this experiment the nitrogen nitrified per day averaged 9 mgrms.; this would give 168 kilos. per hectare of soil weighing 3,000 tonnes, showing how much more favourable the conditions were in the laboratory than in the field.—J. M. H. M.

*The Composition, Treatment and Use of Feces as Manure.* Imperial College of Agriculture and Dendrology, Komaba, Tokyo, Japan. *Bull.* **3**, 1888, 1—25.

LARGE samples of excreta of various origins—peasantry, own population, private houses of the middle class in Japan—were examined, and as the composition in each case is very similar, the mean results are shown in column I. of the following table; column II. shows the composition of excreta of soldiers and students of the nautical college; column III. for comparison, Wolff's numbers for the average composition of European excreta.

The numbers are per 1,000.

	I.	II.	III.	IV.	V.
Water .....	950	944·1	953	963·70	967·7
Organic matter .....	34	40·7	51	14·00	18·6
Ash .....	16	15·2	14	16·3	13·7
Nitrogen .....	5·7	7·96	7	4·20	5·7
Potash .....	2·7	2·07	2·1	2·84	1·37
Soda .....	4·6	3·61	3·9	5·57	5·23
Lime .....	0·2	0·20	0·9	0·03	0·04
Magnesia .....	0·5	0·51	0·6	0·02	Trace.
Iron and alumina .....	0·3	0·61	..	Trace.	0·04
Phosphoric acid .....	1·3	2·97	2·6	0·55	0·44
Sulphuric acid .....	0·5	0·72	0·5	0·77	0·90
Silica .....	0·5	0·37	0·2	0·12	0·07
Chlorine .....	6·2	5·08	4·0	7·88	6·93
Sodium chloride .....	10·2	8·37	6·6	12·93	11·42

THE vegetarian diet of the ordinary Japanese people accounts for the smaller proportion of nitrogen and phosphoric acid and the larger proportion of potash and sodium chloride these excreta contain as compared with European excreta or the excreta of the Japanese soldiers and nautical students, who have a moderate allowance of meat.

COLUMNS IV. and V. in the table show the composition of Japanese urine, IV. of the peasantry, V. of townspeople, which in both cases are more dilute than European urine.

For manure the night-soil is mixed with two or three times its volume of water and left for about ten days in cold weather and five or six days in warm weather to ferment before being applied to the soil. It undergoes decomposition with the evolution of carbonic anhydride and marsh gas, and the

production of large quantities of ammonium carbonate. The Japanese store it in large glazed earthenware vessels. Experiments were made to ascertain whether much nitrogen is lost by volatilisation of ammonium carbonate, with the following results:—

Date of Commencement of Experiment.	Original Percentage of N in the Fæces.	Percentage of original Nitrogen lost, after					
		One Week.	Two Weeks.	Three Weeks.	Five Weeks.	Seven Weeks.	Eleven Weeks.
February 20.....	7.90	2.58	..	5.98	..	..	..
April 24.....	7.97	..	4.63	6.32	10.57	13.02	20.17
July 6.....	7.22	..	5.09	..	12.70	..	..

The loss is so small as not to need precautions for preventing it, when the usual Japanese mode of storage is used. The night-soil is poor in organic matter in proportion to nitrogen, and therefore is made into a compost with vegetable refuse for application to porous soils poor in humus. On the other hand they are comparatively rich in soluble ammonium salts, and so are applied in moderate quantities, frequently, on the non-retentive Japanese soils. Various calculations are given as to the probable produce from a given quantity of night-soil, and it is shown that it is not a complete manure, for, compared with the proportion of nitrogen, both potash and phosphoric acid are deficient, part of the latter moreover being insoluble.—D. A. L.

**Fish Manure.** O. Kellner, Imperial College of Agriculture and Dendrology, Komaba, Tokyo, Japan. Bull. 4, 1889, 5—6; 29.

Waste fish are used as manure in Japan and are prepared either by simply drying in the air or the fish are first boiled in water to obtain fish oil and are then pressed and dried, the second method giving the best manure. The fishes most commonly employed are the herring (*Clupea harengus*) and sardine (*Clupea melanosticta*; *gracilis*) and the following table gives numbers taken from the tabulated results of seven analyses of sardine and three analyses of herring manure:—

—	Percentages in			
	Sardine Manure.		Herring Manure.	
	Highest.	Lowest.	Highest.	Lowest.
Moisture.....	16.36	5.73	17.91	9.43
Organic matter.....	82.94	64.85	74.94	61.45
Ash.....	29.42	10.94	20.64	15.63
Sand.....	11.70	8.04	8.60	6.55
Nitrogen.....	18.16	3.89	17.65	12.18
Potash.....	0.76	0.16	0.88	0.60
S. da.....	0.97	0.33	2.11	0.46
Lime.....	4.61	2.12	5.99	2.56
Magnesia.....	0.76	0.34	0.84	0.67
Iron oxide.....	1.53	0.02	1.99	0.24
Phosphoric acid.....	4.85	2.86	5.96	2.27
Sulphuric acid.....	0.70	0.02	0.34	0.00
Silica and sand.....	10.87	0.79	9.63	2.12
Chlorine.....	0.53	0.22	2.11	0.86

Next to these the following fish are frequently found in Japanese fishmanure:—*Scomber pneumatophorus japonicus*, *Chatoeius punctatus*, *Trachurus trachurus*, *Trichodon stelleri*, *Ammodytis*, *Hypoglossus vulgaris*. Recently the heads, bones, and tails of large fish (*Thynnus sibi*; *pelamys*) coarsely crushed have been employed as manure. Tunny fish manure, from head, bones, fins, and intestines has following percentage composition in two analyses:—Water, 7.23—9.47; ash, 2—28.7; fat and oil, 11.33—14.56; nitrogen, 8.16—5.34; phosphoric acid, 4.25—7.42; lime, 5.14—?; from flesh portions H<sub>2</sub>O, 8.23—12.63; ash, 2—6.16; fat and oil, 18.01—15.22; N, 13.01—10.50; P<sub>2</sub>O<sub>5</sub>, 0.94—2.38; lime, 0.65—?.

Kitchen waste from nine different kinds of Japanese food fish from the sea, dried and finely pulverised, forms a manure of the following composition per cent.:—Moisture, 7.85; organic matter, 63.86; ash, 28.29; N, 6.15; P<sub>2</sub>O<sub>5</sub>, 7.64; CaO, 10.45; MgO, 0.22. On the Japanese coast various sea fish are used for manure, such as small crabs, prawns, and star fish. The following numbers are from analyses of star fish and of a sample taken from a shipload of seaweed somewhat decomposed:—

—	Star Fish.	Seaweed.
Water.....	32.68	50.75
Organic matter.....	20.87	14.21
Ash.....	43.37	..
Sand.....	3.08	21.94

—D. A. L.

*Manurial Experiments with Felspar, Potassium Salts, and Thomas-Slag.* L. F. Nilson. *Tidskrift för landtman*, 1889, 273—281.

NUMEROUS experiments were tried to ascertain the manurial value of felspar as coarse powder, finely pulverised, and as mud; but no decided results were obtained from it with oats on a sandy or moorland soil, although in one instance a small increase is attributable to felspar mud. It is, however, certain that the potash in the felspar, although not immediately active, will become so as the mineral decomposes, which should proceed rapidly in the moorland. This soil contained 18·1 per cent. of mineral matter, 5·3 per cent. of which consisted of lime, 0·15 per cent. of phosphoric acid, 1·37 per cent. of sulphuric acid, 0·6 per cent. of potash; and 81·9 per cent. of organic matter, with 3·7 per cent. of nitrogen; dilute hydrochloric acid extracted from the natural soil, 0·3 per cent. of phosphoric acid, 0·11 per cent. of sulphuric acid, 5·5 per cent. of lime, and 0·03 per cent. of potash. But in spite of this abundance of plant food, owing to it being non-available, good results were obtained by manuring with Thomas-slag, potash (as sulphate), and Chili saltpetre, especially when all were employed together.—D. A. L.

*Investigation of Forest Soil.* E. Ramann. *Wollny's Forschungen a. d. Gebiete d. Agrikulturphysik*, 11, 299—337.

NUMEROUS researches have led to the following conclusions:—1. The specific gravity of the natural soil depends on the amount of humus, the crumbly character, and on the denseness of the layers. It is lowest at the surface on account of the humus, and then increases gradually with the depth. 2 and 3. The crumbling is due to chemical and physical causes, and not to earth-worms, their number being too few. 4. The amount of water in the natural soil is, in fine to medium grained sand, about 3—4 per cent. by weight, corresponding to 4—5 per cent. by volume in the upper layers, and 5—6 in the lower. 5, 6, 7. The distribution of water is the same as in any other soils; plentiful in the humus portions, less in the crumbled portions, and abundant in the denser layers; capillarity acting as usual more strongly in the dense than in the crumbled layers. 8. Impervious layers of clay or very fine-grained sand cause only temporary storage of water after a rainfall, when drainage is possible. 9. The quantity of water retained by the soil is very considerable; a layer of fine to medium grained sand from 7 to 8 metres thick retains as much water as the total annual rainfall yields. 10. The proportion of water falls rapidly in the spring, then slowly and probably reaches a minimum in the autumn. 11. The effect of altitude on the proportion of water is only observable where knolls and small ridges are met with; in a gentle slope the effect of position on the proportion of water is not noticed.

The soil investigated is fine to medium grained sand soil of the northern diluvium, situated on the road from Eberswald to Spechthausen.—D. A. L.

*Sea-Mud and its absorbing Capacity for Lime and Potash.* A. Müller. *Landw. Versuchsst.* 34, 257.

A MOOR in South Sweden consists partly of exposed sea-soil, which is covered all over by an extremely fine mud; this when wet is almost black, but when dry is dark grey, and is characterised by a large quantity of siliceous infusoria. The dry mud contains 0·737 per cent. of nitrogen, corresponding to 3·6 per cent. of organic matter, and 100 parts of ash contain:—20·51 of  $\text{Fe}_2\text{O}_3$  and  $\text{Al}_2\text{O}_3$ ; 0·48 of  $\text{P}_2\text{O}_5$ ; 0·38 of  $\text{CaO}$ ; 0·27 of  $\text{MgO}$ ; 0·25 of  $\text{K}_2\text{O}$  with trace of  $\text{Na}_2\text{O}$ ; and 78·11 parts insoluble in hydrochloric acid, consisting of 59·58 per cent. of soluble silica and 40·42 of quartz and silicate sand. When the air-dried mud is shaken and digested in the cold with lime water or potash, it absorbs 9·95 per cent. of lime or 1·47 per cent. of potash. It would also have great absorbing power for alkaline phosphates or superphosphates, a valuable property considered agriculturally.—D. A. L.

*The Composition and Preparation of Peat Manure.* P. Kulisch. *Chem. Zeit.* 13, 1429—1430.

For several years this material has been extensively used in the vineyards of the Royal School of Fruit and Vine Culture, at Geisenheim. From the results obtained, it seems that the growth of the wood, and, therefore, the fruitfulness, in old and weak vine-stocks is favourably influenced. Experiments were made, during a period of 20 days (in March), to determine the amount of manure obtainable from known quantities of peat. The peat used had the following composition:—

	Per Cent.
Dry matter.....	77·0
Moisture.....	23·0
Ash.....	2·11
Nitrogen.....	0·443
Phosphoric acid.....	0·043
Potash.....	0·017

For each cow (two milch cows) the average amount of peat used was 5·99 kilos. daily, and the average weight of manure obtained daily from each animal was 44·75 kilos. The manure gave the following results on analysis:—

	Per Cent.
Dry matter.....	18·84
Nitrogen.....	0·304
Phosphoric acid.....	0·124
Potash.....	0·565

The analyses of a slaughter-house manure and of a sample of woollen dust to be used for manurial purposes, are also given. The slaughter-house manure consisted chiefly of peat mixed with straw, solid animal excreta, blood, bone-splinters, hair, fragments of horn and flesh, &c. It contained—

	Per Cent.
Dry matter.....	20·59
Nitrogen.....	0·79
Potash.....	0·107

## XVI.—SUGAR, STARCH, GUM, Etc.

*Crystallised Grape Sugar.* E. O. von Lippmann. *Chem. Zeit.* 13, 1474.

THE author has already described and shown (this Journal, 1888, 579) that the products of a dextrose factory working the Cords-Virneisel process are of greater purity than those usually obtained in German factories. Recently he has received from the same factory samples of dextrose low products, consisting of transparent hard reddish pieces formed of numerous more or less well built crystals closely grown together. Analysis gave—water, 4·75 per cent.; grape sugar, 91·84 per cent. (by polarisation) and 92·2 per cent. (by Fehling's solution); ash, 0·219 per cent.; etc. (non-sugar) 3·191 per cent.

The fact that Fehling's solution showed more grape sugar than the polariscope points to the absence of dextrine which is generally an impurity in commercial grape sugar. This absence of dextrine the author has already observed to be characteristic of sugars made by the Cords-Virneisel process.

The sugar consisted of glucose anhydride, and could be heated almost to 140° C. without melting or undergoing alteration.—W. M.

*Record of Experiments at Des Lignes Sugar Experiment Station, Baldwin, La., during the Season of 1888.* C. A. Crampton, U.S.A. Department of Agriculture. Bulletin, 22, 1889.

THE experiments conducted by the author commenced on November 5, 1888, and extended over four weeks or just one-half of the manufacturing season. The proprietors of the factory and of the plantation are Messrs. Shattuck and Hoffmann.

The extraction was performed by a six-roller mill, composed of two three-roller mills set tandem. Each mill was

driven by a separate engine. The second mill was provided with a hydraulic regulator. Maceration was practised all through the season, the water being added from a rose placed above the intermediate carrier. The juice was sulphured and clarified in the usual way and evaporated in a double-effect Rillieux pan. It had horizontal tubes of about 1,225 sq. ft. heating surface. Two 7½ ft. strike pans were used in reducing the syrup to massecuite.

The manufacturing data for the last four weeks of the season, while under chemical control, are given in full detail in the following table:—

	Cane Ground.	Sulphured Juice.	Weight per Gallon.	Weight of Juice.	Sugar in Sulphured Juice.	
	Tons.	Galls.	Lb.	Lb.	Per Cent.	Lb.
Fifth week.....	1,217	292,782	8.86	1,796,650	12.15	224,683
Sixth week .....	1,117	169,822	8.86	1,504,623	12.83	193,043
Seventh week.....	1,392	233,842	8.85	2,069,501	12.72	263,240
Eighth week.....	1,139	191,084	8.84	1,689,183	13.00	219,594
For four weeks .....	4,895	797,530	..	7,059,957	..	900,560

	Sugar per Ton of Cane, obtained in Sulphured Juice.	Sugar in per Cent. of Weight of Cane obtained in Sulphured Juice.	Merchantable Sugar Made.	Merchantable Sugar per Ton of Cane.	Molasses Obtained.	Molasses per Ton of Cane.
	Lb.		Lb.	Lb.	Lb.	Lb.
Fifth week.....	180.2	9.01	182,621	146.4	64,522	51.7
Sixth week .....	172.8	8.64	158,905	142.3	56,523	50.6
Seventh week.....	189.1	9.45	204,820	117.1	105,157	75.8
Eighth week.....	192.8	9.53	189,750	166.6	68,838	60.4
For four weeks.....	184.0	9.20	736,076	150.4	295,240	60.3

The total loss in manufacture during the four weeks was 72,361 lb. of cane sugar (of 100 per cent.) or 8.03 per cent. of the amount of sugar present in the sulphured juice which was taken as the starting point. Of this 8.03 per cent. of total loss, 3.37 per cent. is charged to inversion and the remaining 4.66 per cent. is grouped under the head of mechanical losses.

Experiments made on acid and neutral clarification showed that whilst with the former the colour is better, yet the loss from inversion is decidedly greater with acid than with neutral clarification. The practice of boiling and skimming in an open pan, with either neutral or acid syrup, is strongly condemned, and wonder is expressed that planters should adhere to this practice.

The amount of coal used during the season was 555 tons. The fuel consumption, exclusive of bagasse, is given as follows:—

Pounds of coal per 1,000 lb. sugar .... 946

Pounds of coal per ton of cane..... 128

The author made a few observations and experiments on the process of maceration by means of the addition of hot

water to the canes, or to the bagasse between the two mills. The amount of water thus added at Des Lignes was not subject to any careful regulation, the general idea being to give to the bagasse all the water it would hold. The author concludes "there is no doubt whatever that double milling with maceration could be made as superior to the old method of single milling in cane work as the continuous presses with maceration have been shown to be superior to the method of single pressure in a hydraulic press with beets," but he continues, "it seems hardly necessary to go into the refinements of the method of maceration in cane work, in view of the fact that improvements in this line have been abandoned for the better method of diffusion."

Some interesting experiments were made showing the improvement in cane by standing and ripening. The mill was set in operation too early in the season. The crop was over-estimated, and it was feared that if the campaign were not opened earlier the mill would not be able to handle it before freezing weather set in. The following tables give the analysis of juice from cane on four different cuts at two periods in each case:—

Date of Analysis.	Solids.	Cane Sugar.	Glucose.	Coefficient of Purity.	Available Sugar in Juice.	Pounds Per Ton Available Sugar at 70 Per Cent. Extraction.	Difference.
-------------------	---------	-------------	----------	------------------------	---------------------------	--	-------------

#### STORE CUT.

	Per Cent.	Per Cent.	Per Cent.		Per Cent.	Lb.	Lb.
November 14.....	15.46	13.34	1.09	86.3	11.74	163.8	..
November 30.....	15.83	13.99	0.88	88.4	12.67	177.4	13.6

Average improvement per day in pounds per ton, 0.85.

Date of Analysis.	Solids.	Cane Sugar.	Glucose.	Coefficient of Purity.	Available Sugar in Juice.	Pounds Per Ton Available Sugar at 70 Per Cent. Extraction.	Difference.
BOYLE CUT.							
November 17 .....	15.87	13.82	0.94	87.1	12.41	173.7	..
November 30 .....	16.47	14.88	0.66	90.3	13.89	194.5	20.8

Average improvement in pounds per day per ton, 1.6.

CLARA CUT.							
November 19 .....	15.94	13.80	1.01	86.6	12.28	171.9	..
November 30 .....	16.23	14.75	0.53	90.9	13.95	195.3	23.4

Average improvement per day in pounds per ton, 2.13.

SILLAN CUT.							
November 21 .....	14.80	12.97	0.96	87.6	11.53	161.4	..
November 30 .....	15.77	13.80	0.81	87.9	12.63	176.8	15.4

Average improvement per day in pounds per ton, 1.71.

" " " " " " for all four cuts, 1.56.

From the above tables will be seen the improvement in each case. Taking the average increase of the four cuts at 1.56 lb. of available sugar per ton for each day the cane was allowed to stand, a crop of 10,000 tons would improve at the rate of 15,600 lb. of pure sucrose, equal to say 16,500 lb. per day of merchantable sugar, so that two weeks would add nearly one quarter for a million pounds to the amount of sugar actually obtainable from it. Next season Messrs. Shattuck and Hoffmann will adopt the diffusion process on the Des Lignes plantation.—A. J. K.

*Record of Experiments at the Sugar Experiment Station on Calumet Plantation, Pattersonville, La., 1888—1889.*  
H. Edson, U.S. Department of Agriculture. Bulletin, 23, 1889.

This report gives a very complete and detailed account of the season's work at the above sugar house. The machinery and appliances were all of the best, and the general arrangements admitted of very careful working. The unprecedented (for Louisiana) milling yield of 200 lb. of sugar per ton of cane was obtained. There were two mills employed, the raw juices from which passed to a vessel provided with a paddle, where they were saturated with sulphurous acid gas. The fumes produced by burning sulphur were first cooled and then passed over the surface of water to free them from any trace of sulphuric acid. The juice was then pumped to defecators and lime added. After settling the clear liquor went direct to the double-effect. The skimmings and settlings were re-heated and limed when necessary, and filter-pressed, hard cakes and clear liquors being always obtained. For convenience the season's work is divided into five runs, two on stubble and three on plant cane. In the first run the most noticeable thing was the boiling of molasses containing 33.2 per cent. sucrose and 35.74 per cent. glucose for sugar, and getting a massecuite which grained well and gave 12.06 lb. of commercial sugar per ton of cane.

In the second run the sulphur machine was unfortunately somewhat neglected, and some sulphuric acid was probably produced, as inversion took place to the extent of 1.32 per cent. of the sucrose in the raw juice. The final molasses contained 23.7 per cent. sucrose and 32.6 per cent. glucose. This run was also noticeable for the point to which crystallisation was carried, the glucose apparently not possessing the restraining power commonly attributed to it.

The third or first plant run was the largest, and the cane was the richest. "Maceration, or the addition of water to

the bagasse between the two mills," was commenced in this run and greatly increased the yield of sugar, a gain of 17 lb. of sugar per ton of cane being obtained by the addition of 12 per cent. of water. The water was sprinkled on the cane as it was released from the pressure of the first mill, it being argued that during the expansion following this pressure the bagasse would more thoroughly and uniformly absorb the water than at any subsequent period, a minimum of water thus producing the maximum effect. It is pointed out that although this is a great advantage over ordinary milling, diffusion is clearly the most economical method for the extraction of sugar from the cane. The fourth and fifth runs were not specially remarkable.

In regard to the use of sulphurous acid, the author is very favourably impressed with it as an aid in improving the quality of the output of a sugar house, and although in careless hands it can cause serious loss by inversion, he thinks that when carefully and intelligently applied its use can be unhesitatingly recommended. Experiments were also made leaving the juice slightly acid (with sulphurous acid), and also carefully neutralised. In both cases there was practically no inversion, but the colour of the sugar from the acid liquor was much better than that from the neutral.

Numerous tables are given showing in a most complete manner the working of the sugar house during the season.

—W. M.

#### *Separation of Raffinose from Cane Sugar.* J. fabr. Sucre, 30, 34.

ACCORDING to LOPÈS, ammoniacal acetate of lead precipitates cane sugar, but not raffinose. The possibility of the separation of these two sugars is thus indicated. The author is continuing his experiments on the subject.—H. T. P.

#### *Some Properties of Raffinose.* Beythien and Tollens. Zeits. f. Rübenzucker. Ind. 39, 911, 913, 917.

By the gentle inversion of raffinose (10 grms. of raffinose + 90 cc. of water + 6 cc. of hydrochloric acid of 1.19 sp. gr., heated for 10 minutes to 68° C.) and subsequent treatment of the inversion products with phenylhydrazine, an osazone is obtained whose melting point is identical with that of gluco- or levulosazone. The corresponding sugar is levo-rotatory and is therefore probably levulose. Galactose cannot be directly detected in the inversion products, being, as was pointed out by Scheibler (see this Journal, 1889, 718), still combined with the dextrose. The polarisation of inverted

raffinose is in mean  $+50.94^\circ$ , for  $+100^\circ$  original rotation. ee. of Fehling's solution is reduced by 7.7 mgrm. of inverted raffinose (= 6.53 mgrm. anhydrous raffinose). By the protracted boiling (three days) of raffinose with a solution of strontium hydrate, lactic acid is formed. Under similar circumstances cane sugar also yields lactic acid; but no trace of raffinose is formed, so that Pellet's former assertion on this subject is quite erroneous. Lactic acid occurs in molasses to the extent of about  $\frac{1}{2}$  per cent., and is probably formed by the decomposition of cane sugar during manufacture.—H. T. P.

*The Non-fermentable Dextro-Rotatory Constituent of Honey.* E. von Raumer. Zeits. f. angew. Chem. 1889, 607—609.

Pure honey contains a residual substance after complete fermentation by yeast, which has a decided dextro-rotatory action. This body can be isolated by evaporating the filtrate from the fermented honey, after treatment with aluminium hydrate and repeatedly precipitating by alcohol. It forms a white amorphous mass, having a specific rotatory power  $\alpha_D = 59.3^\circ - 68.06^\circ$  in two preparations (from different sources) examined and reduces Fehling's solution, the amount of reduction before and after inversion having a ratio 1 : 2.62 and 1 : 2.79. The ratio of the rotatory power of the body before and after inversion was found to be 1 : 0.514 and 1 : 0.45. Great care was taken to ensure the purity of the honey examined and to make quite sure that it was free from starch-sugar syrup. Since then this dextrin-like body is contained in pure honey, Sieben's method for detecting starch sugar syrup in honey by the fact that it leaves a dextro-rotatory residue after fermentation (this Journal, 1885, 411) is without value. The exact nature of the non-fermentable constituent of pure honey is still under investigation; it appears to be completely fermentable after inversion and its rotatory power decreases gradually as the inversion proceeds, but at no time does it show any levo-rotatory action, whence it is improbable that levulose results in the inversion.—C. A. K.

## XVII.—BREWING, WINES, SPIRITS, Etc.

*Mealy and Glassy Barley.* L. Just and H. Heine. Landw. Versuchst. 36, 269.

For the examination of barleys the authors employed Rimpau's method, in which the corns are examined by transmitted light; the mealy corns appear dark, and the glassy ones transparent. Seven barleys of German and Swedish origin were examined. The purely mealy and glassy corns of each barley were separated by the above method, and separately examined. The results obtained were as follows:—

1. Absolute weight:—The mean weight of the glassy corns was less than that of the mealy corns.
2. The volume of the glassy corns is smaller than that of the mealy ones, but their specific gravity is greater than that of the mealy corns from the same barley.
3. The moisture percentage is the same for mealy and glassy corns of the same barley.
4. The amount of ash is somewhat smaller in the glassy than in the mealy corns. Weight for weight, however, the glassy corns in most cases contain a higher amount of ash.
5. The glassy corns contain more nitrogenous compounds than the mealy corns of the same barley. Weight for weight, however, glassy barley may contain less nitrogen than mealy barley from the same sample.
6. The germinating energy is all through less in glassy than in mealy corns, but the total number of corns capable of germination is a trifle larger for glassy barley.

According to the authors, no direct connexion exists between the degrees of mealiness of various barleys and

their weights, and the percentages of ash, and especially of nitrogenous bodies, contained in them. The same may be said of the germinating energy and the percentage of corns capable of germination.—H. T. P.

*Studies on Diastase.* C. J. Lintner and F. Eckhardt. Zeits. f. d. ges. Brauw. 12, 389.

As the result of their experiments the authors find that the ferment of ungerminated grain (in this case, barley and wheat) differs considerably from the diastase of malt. At temperatures above  $35^\circ\text{C}$ , the former has a weaker fermentative action than the latter; at temperatures below  $35^\circ\text{C}$  the reverse holds good. The observation of Reyehler that a ferment is formed by the action of dilute acetic acid, &c., on wheat flour or gluten (unmedin) is confirmed by the authors. This formation of a ferment by the action of acids must not be confounded with the formation of diastase during germination. The action of Reyehler's (see this Journal, 1889, 407) ferment solutions is similar to that of wheat and barley extracts. To prevent mistakes, the authors propose that the name "diastase" be applied to malt diastase alone, and that the ferment of ungerminated grain be termed barley diastase, wheat diastase, &c.—H. T. P.

*The Colouring-Matter of Red Wines.* R. Heise. Chem. Zeit. Rep. 13, 283.

In the separation of the colouring matters of wine, two methods are chiefly employed: precipitation by means of basic acetate of lead, and direct extraction of the colouring matter. The author has employed the first of these methods. In Mulder's method the lead precipitate is decomposed by means of sulphuretted hydrogen, and the lead sulphide is extracted with acetic acid and alcohol. The author finds that the colouring matter thus obtained always contains lead. Glénard decomposes the lead precipitate with an ethereal solution of hydrochloric acid gas. Two different colouring matters are obtained in this manner, A and B. A is insoluble in absolute alcohol, B is soluble. The lead precipitate from wine is partially soluble, partially insoluble in glacial acetic acid. The insoluble portion corresponds to the colouring matter A above described, the soluble portion to B. A directly prepared extract of fresh ripe grape skins contains a colouring matter identical with B. Gautier's statement that grape skins contain colourless, readily oxidisable tannins, could not be confirmed. According to Nessler, not only the alcohol formed during fermentation, but especially the acid and the temperature have great influence on the solubility of the colouring matter. The results obtained by the author rather tend to show that the acid has not so much an effect on the solubility as on the intensity of the colouring matter. The tanning matter of wine, oenotannin, consists, according to the author, of three substances, gallotannic acid, quercetin, and an unknown body.

Grapes and red wine contain the same red colouring matter B. The lead precipitates contain in addition considerable quantities of A. The latter is chiefly contained in the lees of wine, and may be obtained from B by long boiling with hydrochloric acid. A can exist in the wine in solution only in very small quantity. It is probably formed during the treatment of the wine or grape extract with basic lead acetate. Possibly A is an oxidation product of B, its formation being favourably influenced by the alkalinity of the precipitant. The variations which occur in the reactions of wines are partly due to the colouring matter B, which is easily affected by external conditions, and partly to the amount of other substances which accompany the colouring matter. The ratio of these bodies to the colouring matters is continually changing as the precipitation of the colouring matter of the wine goes on.—H. T. P.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

### (A).—CHEMISTRY OF FOOD.

*The Chemistry of the Manufacture of Preserves.* W. Reuss. Chem Zeit. 13, 1428—1429.

The moiré-like film which is often found on the interior surface of preserve tins has been ascribed by Beckurts to the formation of sulphide of tin. He proved this in two ways:—

(1.) The film was dissolved in ammonium sulphide, and the tin precipitated as yellow tin sulphide by the addition of excess of sulphuric acid.

(2.) The film was removed by friction with cotton wool, which was subsequently treated with hydrochloric acid. The sulphuretted hydrogen evolved was detected by the yellow colour it imparted to a drop of silver nitrate solution spread on filter paper.

The author finds these reactions to be worthless for the purpose in view, since they are both yielded by perfectly clean, untarnished tin-plate. Even chemically pure tin yielded the second of the above reactions. This is no doubt due to the presence in the tin of traces of arsenic, antimony, or phosphorus, which yield hydrides capable of discolouring silver nitrate. The author proposes the following test:—Pure dry sodium carbonate is dusted on the surface of the tin-plate and well rubbed in with cotton wool. The sodium carbonate is afterwards fused with potassium nitrate, and the solution of the fused mass tested for sulphuric acid with barium chloride. The formation of moiré films is very common in the case of all vegetable preserves. This is no doubt due to the more or less acid nature of all plant juices. During sterilisation and subsequent storage, the organic acids act on the surface of the tin, forming the moiré film, in the same way that this appearance is produced for certain purposes, by means of mineral acids. In most cases, therefore, the dark film consists of minute tin crystals. In a few instances the author was able to detect sulphur in the films.—H. T. P.

*The Corrosion of Nickel-cooking Vessels by Organic Acids.* A. Rohde. Arch. f. Hygiene, 9, 331.

In all former researches on this subject the chemical corrodibility of nickel has been practically neglected. In his experiments the author used acid solutions of known strength. It appears to be not improbable that considerable quantities of nickel may pass into solution during the preparation of, especially, very acid foods in nickel utensils, and theoretically at least, the regular introduction of nickel into the human system might be attended by serious consequences. Taking into account his own observations, as well as the physiological experiments with nickel salts of Geerkens, Laborde, and Riche, the author is, however, of opinion that nickel cooking utensils may be employed with perfect safety, provided they are obtained from a reliable source.—H. T. P.

*Experiments on Blue Milk.* L. Heim. Arbeiten a. d. kaiserl. Gesundheitsamte, 5, 518.

MILK on standing shows small blue spots, which become gradually larger, and finally cover the whole surface, the milk turning at the same time sour. The phenomenon is due to bacteria, which have been isolated by Löffler. The present author has examined such bacteria more minutely. He finds them to consist of short rods with rounded ends. Formation of spores he was never able to observe, and subsequent experiments show spore formation to be improbable. By means of gelatin, &c. the bacteria lose their property of colour formation, and can then no longer render milk blue. At a temperature of 55° C. they die in ten minutes, at 75° C. in five minutes, and at 80° C. in one minute. This fact is opposed to the formation of spores. At 30° C. the growth was much weaker, and at 40° C. the bacteria died in a comparatively short time. In a 3 per

cent. solution of sodium carbonate they died in three hours, in a 10 per cent. solution only five minutes were necessary, in salicylic acid (1 to 300) 30 minutes, and in 5 per cent. caustic soda solution 45 seconds. In 4 per cent. boric acid solution they were in good condition, even after five days. The results of these experiments speak also against the formation of spores. Of course, if the experiments be made in the milk a much longer time is necessary to bring about the above results.—T. L. B.

### PATENTS.

*Improvements in Farinaceous Food for Animals.* A. Brunier, Marseilles, France. Eng. Pat. 19,003, December 29, 1888. 4d.

MEAL from the nigella or fennel flower and from maize husks is made into a mixture with meal obtained from other kinds of grain, and with any suitable oilcake. As an example, a mixture is made of 40 parts of nigella meal and 10 parts each of maize husk meal, bean meal, barley meal, oilcake, decorticated earthen meal, and earthen husks.—J. M. H. M.

*Improvements in and relating to the Treating and Preserving of Fish.* W. G. Pursell, Leith. Eng. Pat. 1033, January 19, 1889. 4d.

AFTER the fish have been cleaned, they are first smoked and then treated with boric acid or borax, or some compound containing one of these substances.—E. E. B.

*An Improved Process of and Means for the Preservation of Milk.* F. McIntyre, Glasgow. Eng. Pat. 1423, January 25, 1889. 6d.

THE cows are milked into a sterilised receiving vessel, precautions being taken to prevent contact with atmospheric germs. The teats between the milkings are covered with an elastic material or with an antiseptic solution, such as potassium permanganate or sodium silicofluoride, alone or with vaselin; and before milking, the teats are washed with the same solution. The milk is drawn from the teats by the insertion of sterilised metallic trocars, the orifices at their ends being capped with india-rubber. The trocars are inserted into the teats after removing the caps, and by means of india-rubber tubes on the other ends the milk, obtained by hand-milking in the ordinary way, is led into a receiver previously sterilised by steam or other heat, and having an exit tube for the air fitted with cotton wool or other filtering material, and coated internally with glycerin or other sticky liquid; or the entrance of germ-laden air may be prevented by interposing a sterilising liquid, or by other means.—J. M. H. M.

*Improvements in Apparatus for Assimilating Cow's Milk to Human Mother's Milk.* R. W. Seathing, Birmingham. Eng. Pat. 6318, April 13, 1889. 8d.

THE milk is boiled in a vessel constructed so that the milk is kept whilst boiling in a state of circulation. The vessel is heated by means of a spirit-lamp, and to prevent the milk from charring a plate of perforated iron is placed between the lamp and the bottom of the vessel.—E. E. B.

*Improvements in or relating to the Preparation of a Beverage adapted to be used as a Substitute for Coffee.* A. W. Rehnstrom, Malmhammar, Sweden. Eng. Pat. 14,970, September 23, 1889. 4d.

WHEY, milk, or a mixture of both, is boiled down in a vacuum apparatus or otherwise to a pasty consistency, then formed into cakes, dried at not above 100° C., and afterwards cut into pieces about the size of coffee beans, and roasted.—J. M. H. M.

## (B)—SANITARY CHEMISTRY.

*On the Examination of Water for Domestic Purposes.*  
F. Fischer. *Zeits. f. angew. Chem.* 1889, 502—505.

THE author shows by quotations from various authorities how diverse are the opinions held as to the kind and amount of examination needful for passing judgment on the fitness or otherwise of water for drinking. Since the discovery of the cholera bacillus by Koch, physicians especially have been prone to base their judgment on the results of bacteriological tests, a course which would be very praiseworthy if the conclusions drawn were not so widely at variance. Plagge and Proskauer discard a chemical examination, and insist on the water containing no more than 150 germs in 1 cc. by Koch's test, whilst Koch places the limit at 300, and Pfeiffer at 1,000. On the other hand, several investigators have shown that a water containing but few germs when freshly drawn from the spring developed large numbers on standing a short time at the ordinary temperature. Again, it has not yet been shown to be possible to distinguish between harmful and innocuous germs by any practicable test. The only condition generally agreed upon is that a water to be used for domestic purposes should not be contaminated by decomposing matters of human or animal origin. Animal excrementitious matters cannot be identified as such in water, but their ultimate products of decomposition can be determined by chemical means. In the case of spring or river water some of these substances, such as phosphates, ammonia, and potassium salts, may be absorbed by the soil over which the water flows, but the chlorides and nitrates will remain in the water to form a clue to previous contamination. Accepted that a determination of organic nitrogen, ammonia, nitrates and nitrites, and chlorine may be of great importance in forming an opinion on a water, still there can be no standard with which the figures may be compared. Even the results of chemical and bacteriological examination taken together can only be taken to afford an indication that the water may have been contaminated. In all important cases, especially when the water is to be supplied to a town, a reliable judgment can only be arrived at after a consideration of all the circumstances afforded by an inspection of the source and its surroundings as well as the results of examination of samples collected by the expert himself.—G. H. B.

*London Sewerage and Sewage.* Sir Robert Rawlinson, K.C.B. *Jour. Soc. Arts*, 38, 65—82 and 141—156.

IN introducing the reader of the paper the Chairman, Sir Henry Roscoe, M.P., said that in his first report to the Metropolitan Board of Works he had remarked that the use of deodorants ought to be regarded only as a "temporary" expedient, and that the sewage, whether clarified or not, must either be filtered through land or discharged into the estuary at a point not higher than Sea Reach. In a pamphlet laid before the Main Drainage Committee he had expressed his opinion that from a chemical point of view the present process of precipitation did not effect any improvement in the quality of the effluent, that the arrangements at Barking were based on false principles, and that the barging the sewage out to sea was a mistake.

He concluded by expressing his satisfaction that the Main Drainage Committee regarded as a probable alternative to the present scheme at Crossness and Barking the conveyance of the sewage to the sea upon the Essex shores by some such plan as that already sanctioned in the Act of 1865, and that in that event the present works might be available for storage purposes.

Sir Robert Rawlinson: The River Thames flows over beds of oolite, chalk, and London clay, covered mostly with water-washed gravel. These gravelly sub-areas along its course act as natural filter-beds, and justified the poetic title of "the Silvery Thames." The dry weather flow is practically spring water, and frequent floods carried down detritus from the clay and chalk, which acting as a disinfectant purified rather than polluted its waters. The River Lea was its most important northern tributary, having a watershed area of 500 square miles, and this, he thought,

ought to be comprised in the metropolitan main drainage area for purposes of purification.

For all sanitary purposes modern London ought to date from the year 1801, when water-closets were introduced, main sewers were flat-bottomed and arched, and house drains were built of brick from 1 to 3 ft. in diameter without ventilation and untrapped. Fever and disease followed of course, so Parliament passed an Act forbidding communication between these drains and the main sewers, and the remedy suggested at that date was that of cesspools within the basements of houses.

"Dry wells" or "dumb wells," as they were variously called, were universally adopted, and when full to overflowing were often emptied into the sewers with the connivance of the authorities. Under Windsor Castle he himself had found 53 such cesspools or "dumb wells" sunk in various parts of the basement, and under the Board of Health offices at Gwydyr House, Whitehall, he had found three such wells overflowing with putrid sewage.

Such was the condition of London and other large towns in 1848, when the first Public Health Act was passed.

Its local administration was carried on by 300 local bodies, under 250 different local Acts, until 1855, when the Metropolitan Board was established for the especial object of constructing a main sewerage system to prevent further pollution of the Thames, and purify its waters. Already millions had been expended for this purpose, but no provision had been made for conveying as much as possible of the water derived from rainfall on the surface, or from springs beneath it, directly into the river. This had necessitated extra sewers of relief. Moreover, the low-level intercepting sewer under the Thames Embankment would not do its work; its dimensions and capacity having been sacrificed to the Underground Railway, which had been allowed to usurp its site.

This made it necessary to provide storm overflows, which caused pollution of the Thames, contrary to the purpose and provisions of the Statutes under which the Board had been constituted. In the result, periodical floods and pollution were inevitable, and Londoners must bear it patiently. After many experiments, Barking and Crossness were chosen for the position of outlets to the river, in opposition both to public opinion outside and to the decision of the special referees appointed to investigate the subject under the powers of the Act. The total cost of the works, including 82 miles of intercepting sewers, equal to a flow of 400 millions of gallons of sewage daily, storm overflows, reservoirs, and other subsequent additions, was 6,000,000*l.*, and after all this expenditure it was discovered that the reservoirs at Barking and Crossness had not sufficient storage capacity to store sewage until the tide had turned, so that crude sewage forced its way into the river, within the limits of the Metropolis, on the flow, an effect which it was the especial purpose of the Acts to prevent.

London covers an area of 117 square miles, the population being about 5½ millions, residing in 750,000 houses. There are some 2,700 miles of streets sewered, and yet London is not, in its sanitary works, perfect, though on the whole it is the best drained city in the world.

It cannot be said that with all this expenditure and labour the Board performed the work which was the object of its existence, viz., to prevent the continual pollution of the Thames, and their final report proves that they have misinterpreted their Acts and misapprehended their instructions. As to the disposal of the sewage; the authors of those Acts evidently contemplated a profitable disposal. How, he asked, is this possible if it be turned bodily into the Thames? It is true that the old Board tried to find others to do this most important part of their work; indeed, a company was formed with this object in 1865, and obtained an Act under the title of the "*Metropolis Sewage and Essex Reclamation Act.*" It failed to obtain public support, expended 250,000*l.*, including a preliminary deposit of 25,000*l.*, and came to naught. Then came the great "mud contest" 10 years later, the Conservators complaining "that mud banks had been formed at the outfalls," and calling upon the Board to remove them by dredging, as provided by their Act. The Board replied that there were

no sewage sludge banks to be dredged, and the Conservators were defeated in their arbitration. Results have proved that there are fully 1,000 tons per day at Barking alone, and where did that pass, if not to form mud banks in the river channels?

Then came the formidable Royal Commission in 1882, which made inquiries and published reports, with conclusions and suggestions as to disposal of sewage. The Board accepted one part of the recommendations, neglecting the vital one, viz., that the sewage, as a permanent measure, should be purified by intermittent filtration through land. They adopted a separation process, let contracts for mud tanks and mud barges, using chemicals at great cost to do what chemicals cannot do, viz., produce an effluent which will not pollute the river in hot weather!

There have been many schemes propounded, commercial and scientific, but the Board stood to their plan, and left it as a legacy to their successors.

Barking had already protested and complained of the nuisance long before—it was his duty to inquire and report,—but the evidence of nuisance to Barking town failed, and he so reported, though he saw that the river was grossly polluted above and below both the outfalls.

With respect to sewage treatment, the word “disinfect” cannot properly be employed. To “disinfect” the sewage of the Metropolis would cost millions sterling per annum, and according to Dr. Parkes the most powerful “disinfectants” did not give safe results. “Clarification” may be accomplished “temporarily” by chemicals, but will not then produce permanent purity. It will cost 1,500*l.* to 3,000*l.* for each million of gallons per diem, and even 1,500*l.* per million of gallons will amount to 225,000*l.* per annum for the sewage of the Metropolis, whilst with mud barges and other attendant expenses we may calculate the cost at 450,000*l.* per annum, taking the amount of sewage sludge at 28,000 tons per week, which he believed was not an over-estimate.

Experience in this country and elsewhere serves to show that sewage irrigation is the cheapest and best plan, and it has been practised all over the world time out of mind.

Taking the solids in London sewage to amount to 10 tons of sludge per million gallons, we have 547,500 tons of sludge per annum to be removed. There will be in this volume 1,425 tons of water to every 75 tons of solids. Did it ever before enter into the heads of any body of men, engineers or vestrymen, to perpetuate such operations?

Moreover, in hot weather tanks and barges will become putrid, and if disinfectants be used the cost will be very high, whilst land would disinfect fresh sewage at once, and thus save the cost of chemicals, while that which is allowed to pass into the sea will be at once diluted and dispersed.

Meanwhile, the cost bequeathed to the County Council, including workmen's houses and the new sand barges, will exceed 1,000,000*l.* under the head of capital outlay, and that without preventing the continued pollution of the Thames. Such a legacy is equivalent to an entire herd of white elephants!

The expense of taking the crude sewage to the sea at Foulness Island by a new conduit 46 miles in length, with pumping engines and all other apparatus, will cost far less, without taking into account any profit from sewage farming or payments by farmers utilising it on the way. But we have sufficient experience to warrant the belief that it would be cheaper and better to bring the sewage from the south side under the river by a tunnel to Barking, and transport the whole, once and for all, to the North Sea, and then to let reclamation of land and sewage irrigation follow.

Instead of these proposed mud barges or tank steamers it will be possible to send sewage containing 90 per cent. of water to any distance in open troughs or pipes. Sand is so conveyed in Holland and on the banks of the Suez Canal, and this form of conveyance dispenses with the use of sludge vessels, as now proposed.

This or some similar work must be carried out, and the Crossness and Barking outfalls must be so altered and modified as not to pass any sewage at those points into the river.

The plan is feasible, and will supersede the use of costly chemicals altogether, whilst the grand old river, now a loathsome ditch, will become a highway of wholesome water.

Mr. J. G. Rhodes (late chairman of the Main Drainage Committee) contended that the Metropolitan Board had as far as possible carried out the recommendations of the Royal Commission, and in order that the works at Barking might have a fair trial they ought to be allowed to remove the sludge deposited. They had to remove daily about 3,000 tons of sludge, and the question was what the best method of doing so, at all events for the present. The two sludge barges already purchased were clearly inadequate. He admitted that the state of the river last summer was disgraceful! Its bed for a considerable distance above and below the outfalls was covered with sludge. This last summer all “hubbled up” and caused what was termed “black water,” and such was the condition of things that it was necessary to deodorise the river with one of the ships.

If the sludge were not removed next summer the same evil would be repeated and intensified. The public did not appear to fully apprehend the danger of pouring sewage in its crude state into the river. The committee's recommendation is the only practical course at present.

Sir Frederick Nicolson, Bart. (chairman of the Thames Conservancy Board), fully confirmed Mr. Rhodes' description of the state of the river. He was pleased to find that the County Council now admitted that which the old Board had persistently denied. Looking at the matter from a seaman's point of view he was firmly convinced that if these plans went on there must be a series of shallows formed in the part of the river near the outfalls.

Mr. Eneas Smith, as a member of the Main Drainage Committee, was dissatisfied with the present condition of things, and declined to order any more sludge ships. He had no faith in chemicals; and as to the expense, that did not rest on the shoulders of the County Council. Unfortunately there was no alternative but to finish the contract, so far as Barking was concerned. With regard to Crossness, that was a matter for further consideration. There ought to be full and complete inquiry before any further expenditure were incurred.

Dr. Alfred Carpenter commended the paper, and said that the great principle in dealing with sewage was to keep it in motion until it was delivered as fresh as possible on to the land. If this were done they could produce in abundance the meat and milk so much needed in London. The ratepayers must not look for profits, but thousands of acres of lands now worth 5*s.* might be made to yield an average value of 5*l.* per acre. There was plenty of land to be had at Canvey Island, or on some of the wastes round London.

Colonel Jones, V.C. (of Wrexham), said that sewage farming at Wrexham was a success, and his present farm had by means of irrigation during the past 18 years become so enhanced in value that the Corporation declined to pay the price now demanded for its acquisition. They preferred to take another farm two miles farther away from the town and spend money in preparing it for sewage irrigation. The tenant of the new farm was delighted to take the sewage, and if an experiment were made at Canvey Island on a small scale there would soon be a demand there for the privilege of utilising it. Mr. Bailey Denton and himself had already offered to relieve the County Council of London of the expense of building sludge ships, and to carry the semi-liquid sludge down to that island by 12-in. pipes in duplicate, four feet above the surface along the Essex shore; there was no difficulty in driving the whole of the sludge along the pipes, and if it were not liquid enough it might be made so.

Dr. C. Drysdale instanced what had been done by way of irrigation both at Paris and Berlin.

Sir Robert Rawlinson reiterated his conviction that “clarified sewage” was truly polluting sewage, and would cause mischief when it passed into the river.

At Leamington the A. B. C. people proposed to make a valuable manure from sewage, but they were driven out of the place because their effluent polluted the river, and they were restrained by injunction.

Mr. W. C. Sillar strenuously denied the truth of this statement. Their system was tried at Leamington for two years, while land was being prepared for irrigation. As a fact, they saved the town from an injunction, and were publicly thanked by the Corporation for the services rendered during that period.

The discussion on Sir Robert Rawlinson's paper, adjourned from December 18, was resumed, and an *Appendix* to the paper read.

Further tabulated statements had been prepared showing the increase of population since 1855 in the Metropolis, together with the current percentage of mortality in London and five other large cities from 1865 to 1888; another table set forth the population and death rate of London year by year. As the population increased the death rate diminished, the reduction being 6·5 per thousand during a period of 48 years, and the death rate in 1888, 18·5 per thousand. The lesson to be drawn from these figures was that great works of sanitary improvement conducted to the material advancement of the community, notwithstanding their cost and the unjustifiable grumbling over payments to professional men. Imperial and local governments were equally to blame in this respect. The new London County Council had a great work before it, and they could not cheapen it by underpaid professional assistance. The London sewerage system was not yet complete, since the population had nearly doubled since 1855, and had outgrown the works. Sewage tanks, pumping stations, and main sewers on both sides of the river were too small, and must be duplicated. Moreover, further relief sewers and storm overflows were required. Such things as these were the ordinary incidents of great engineering enterprises, and were inevitable at certain stages of their progress. The Metropolitan Board of Works had done great things, and the one great and prime work left undone was the freeing the Thames from pollution.

As to *chemical treatment* of sewage, all inquiry and experience lead to one result, that the richest sewage, unmixing with detritus, would cost the least (to get rid of it) when applied to land in broad irrigation. Excess of water was a disadvantage when land was not available. There was land enough between Barking and the sea to utilise the whole sewage of London either on the way or at the terminus of the Maplin Sands by washing the sludge and passing the clarified water into the sea. Chemicals would not "purify" sewage, nor in his opinion had sludge any commercial value, as shown by the history of Knostrop Works at Leeds, which had proved a costly failure.

A letter from Sir Edwin Chadwick, K.C.B., was then read. The writer said that Sir Robert had overlooked the fact that 20,000 acres in Essex, and 7,000 acres in Middlesex had been offered by practical agriculturists for the disposal of London sewage before 1858, and that sewage-farming was a profitable investment. He might have referred to Bedford, Malden, and Croydon as examples of fertilisation, and where food for five cows instead of one on the same land could be produced. The ratio of fertility might be stated as follows:—That whilst common culture was as 1, market-garden culture was as 3½, and liquefied manure culture as 5. On the subject of London drainage it was agreed that fully two-thirds of the existing sewage was pumped in to be pumped out again, and wasted. That wasted volume should be reduced in the sewers of half the Metropolis for the sake of economy and sanitation. Engineers long ago had been constrained to reduce the size of their drains, for houses as well as sewerage mains, in order to make them self-cleansing. This had been forgotten or "Sir Robert" would not have provided six-inch drains for a single house, which were enough for the drainage of 1,600 houses! He gave him credit for a partial adoption of the separate system by his recommendations at Berlin, Dantzic, and Paris. It was not just to speak of London "as the best-drained Metropolis" in Europe, it should rather be the "least badly-drained"! As to the sanitary condition of first-class houses recently built, not above one in three was free from defects, whilst in the dwellings of wage-earners the mortality was fully doubled by preventable causes. The author of the paper had done good service all over the world, especially on the Sanitary

Commission of the Indian army, by promoting a reduction of the death-rate from 67 to 14 per thousand; in Lancashire also, during the cotton famine, and for these great services the Treasury had awarded him only a third-rate pension of 600*l.* per annum! As to board schools, children were kept in health by constant washing, and changing the air every 10 minutes. This was his own (Sir Edwin's) work, but the reader of the paper did not seem to be aware of it.

Sir Robert Rawlinson explained that he had not mentioned these things—though he knew them well—because they were not germane to the subject of his paper from the point of view of an engineer.

A letter was then read from Mr. John Phillips, the oldest living sanitary engineer of the Chadwick school. He described the condition of London sewerage 50 years ago. Wide leaky sewers, flat-bottomed, full of deposit, opening into the natural watercourses, thence into the river, until it became a perpetually oscillating body of filthy water flowing between banks covered with sewage slush. This was the result of removing both sewage and rainfall together in the same channels, and by this means the ground, air, and water were alike polluted. The houses had leaky cesspools and leaky brick drains which reeked with filth. They emptied the cesspools and abolished them and laid down pipe drains for the first time in the houses and along the watercourses. The result was foul gas everywhere, whilst the river was poisoned ten times worse than before by the augmented volume. This led to a great outcry and to the main drainage of the Metropolis, which they were now discussing. He urged the Commission of 1849 to adopt the separate system when there was time and opportunity to do it extensively. The Commissioners rejected his advice for lack of knowledge of the subject. In his opinion the perpetuation of the old system of combined drainage in the same channels was a national calamity. The separate system suggested by himself is now adopted by the London County Council, but too late, and also by all sanitary authorities of understanding. With respect to the tunnel scheme referred to in the paper, he had proposed one in 1849. It was intended to be laid in an uniform curve from East Ham, threading the windings of the river up the valley as far as Windsor, and to be an intercepting channel for the sewage of the whole district instead of the Thames. From Twickenham to East Ham, 19½ miles, the fall would have been 49·25 ft., or 1 in 2,090, and its depth at the outfall would have been 65 ft. in the London clay . . . . . bored through the solid clay, and "not through water-bearing strata." This tunnel could not have caused the mischief imputed to it. Besides the tunnel, it was intended to lay from west to east on both sides of the river two other intercepting mains—with their outlets also at East Ham and Plumstead Marshes—where the sewage would have been lifted and conveyed by mains through Essex to the North Sea, and through Kent to the English Channel. Farmers on the way might have taken the sewage for irrigation. The result of this scheme would have been abundant meat, milk, and vegetables for the people, and the Thames unpolluted from Windsor to the Nore!

The rainfall would have gone into the river by the existing sewers, after diverting the sewage from them so far as practicable. If this project had been carried out there would have been no need of these proposed open gigantic sewage conduits, as the Thames would have been restored to its pristine purity. He was the inventor of the egg-shaped or parabolic sewer, and had determined the rate of the flow of sewage, so as to preclude the depositing of silt, at 150 feet per minute. The egg-shaped sewer was now universal, and his formula for non-deposit flow of sewage, together with the proposed separate system, had been adopted in all modern town drainage schemes. He agreed, with Sir Robert, that these standard improvements deserved recognition.

Mr. Clare Sewell Read said that cheapened nitrates at about 1*d.* per lb. had driven sewage fertilisers out of the field. A point in favour of sewage farming was the introduction of "silos." This enabled the farmer to store his grass in any quantity until it was wanted. Sewage

grass made capital ensilage, and produced the best possible milk. As to manure from sewage sludge, he had tried it, and it did no good to his crops. If fortified by other fertilisers it might be a good vehicle for distribution over the land. Of itself, it was not worth the carriage of five miles. He was in favour of broad irrigation when they could get the land. If not, a good deal was to be said in favour of precipitation processes. With respect to the alleged famine of milk in London, he could supply abundance of it at 6d. per gallon. In town they would have to pay 2d. per pint for it. Who got the profit? Certainly not the farmer. Sewage was a nuisance and they must get rid of it. As to the great conduit to the North Sea, if the farmer could tap it on the way and use it for his land only *when he wanted it*, it would do great good; when not required the surplus could be delivered into the ocean. The Craigentiny meadows near Edinburgh were let at a fabulous price. The land was porous, and when it did not take the sewage it was discharged bodily into the sea.

Mr. W. C. Sillar: Although the author of the paper spoke with authority, some of his conclusions were at variance with the facts. Sewage treatment consisted either of filtration, irrigation, or precipitation. In the old days precipitation meant nothing but treatment by lime, which was destructive of manurial value in the sludge and offensive withal. If that was what the author meant by precipitation he rightly preferred irrigation; but the world had gone round since that day, as might be seen at Kingston-upon-Thames—above Teddington Lock. The effluent, good enough above Teddington, was good enough also for Barking or the Clyde. The author did not believe in the efficiency of chemical systems, nor in the value of sludge, but Wellington College, Aylesbury, and Kingston-on-Thames had come to a different conclusion, and had expressed it in official reports. "Sir Robert" himself thought differently when he visited Aylesbury many years ago. He was pleased then, but his official sense of responsibility restrained him from expressing a preference for any one process over another. Against the unsupported statements of his paper he would place the opinions of the medical officer of health of Kingston and the public declarations of the town clerk of Aylesbury from time to time during the past ten years.

With regard to the value of the sludge, he could prove his case by volumes of testimonials from farmers and gardeners, who had repeated their orders from time to time.

Portable manure had been made from sewage for 14 years. It was made and sold at Kingston-on-Thames, and the mayor of that town was there to certify the fact. The author had said that "the Native Guano Company" had been driven out of Leamington by an injunction—or the fear of one. The facts were, that an injunction had been obtained long before against the Corporation of that town for a nuisance arising from the working by them of a different process, and the A. B. C. Company was then called in to supersede that process, and help the Corporation over their difficulties. They did so successfully until the works were completed, and were thanked for it. He could not believe in Lord Warwick's threat of an injunction, for the company never had reason to fear it. He objected to the "open conduit" proposed. There would be deposition in a sluggish stream of 46 miles in length, and the liquid would become stale and offensive before it reached the sea. When it did it would float, not sink, and the slime upon the beach would stink abominably in hot weather. This project might be useful if there were no alternative, but there is an alternative; and the County Council were justified in making the experiment of precipitation, and giving the works at Barking a fair trial. If it failed, a better scheme could be found and adopted in lieu of it hereafter.

Dr. Dupré, F.R.S., objected to feeding men with things cultivated on sewage farms. As to Berlin, they could not compare a sand waste to the heavy land of our sewage farms. The author was wrong in his estimate of the cost of the Board of Works present scheme. If it cost more than 118,000l. per annum it was not the scheme as recommended to and accepted by that Board. It had never been alleged that no sludge was sent into the river, nor did they deny that the so-called sewage banks were sewage-mud. At one

inquiry others admitted that 250 tons a day went in, at another 180 tons, and 207 tons. Precipitation processes "clarified" water, and removed sludge, and the minimum of material for such purpose should be ascertained and used, seeing that every grain of material added to a gallon of London sewage resulted in 100 tons of wet sludge per day. All the lime used would be effectually precipitated. None would pass into the river. By clarifying the sewage it reduced the polluting effect to about one-half; that is, the pollution of the river was reduced from the effect of 5,000,000 people to that of 2,000,000 people. In summer the effect was vastly greater, as every chemist who had investigated the subject knew; in cold weather the sludge matters remained and settled down unaffected, and when summer came they had to defecate the sludge of the previous eight months, besides the sewage of the day. In the hot weather the sewage of 5,000,000 people would be reduced to that of 1,000,000 people, and when London had reached a population of 10,000,000 inhabitants the polluting effect would be equal to that of 2,000,000 people. If the County Council were wise, they would accept the scheme handed down to them. By the year 1914 they might reduce the polluting effect to nothing. With respect to deodorisation, the production now of manganese was enormous, and the price had gone down from 40l. per ton, without a guarantee, to 8l. per ton with one.

Dr. Thudichum had noticed many inaccuracies in the paper. As to the cost of clarification he had charged almost double the actual expense.

The weight of sludge would average 3,500 tons per day, containing 90 per cent. of water. The London sewage amounted to 272,750,000 tons per annum, and if it were correct that land under favourable conditions could not take more than 5,000 tons per acre annually, then it would require 55,000 acres of land to take the whole sewage of the Metropolis! If Dr. Lethby were right, it would require 200,000 acres—not quite three times the present area of London; so that to lay London sewage in a farm was chimerical. The sludge steamers were fine vessels of 2,000 tons each, and well appointed. He had been on them, and it was untrue that they became putrid and required disinfection. The cost of wages would be 40,000l., not 50,000l., per annum, and chemicals for precipitation would cost 20,440l. per annum. He put the total cost of treating the sewage and taking the sludge to sea at 130,000l. per annum. Give the scheme a trial, otherwise the 1,000,000l. sterling spent would be sunk altogether.

Professor Corfield approved the conclusions of the paper. London was the healthiest city of the world, because the excreta were removed continuously. Although removed from London it became a nuisance in the Thames, and it now remained to get rid of the nuisance there by carrying it practically to the sea, and by this measure the County Council would justify its existence.

Mr. Arthur Angell denied that the sewage would be got rid of when it came to the end of the proposed conduit. It would not mix with the sea, and could not be disposed of in that manner. It was simply shifted from one situation to another. Sewage farms were a nuisance in many places, and at Croydon, the best managed of all, they lost 12,000l. per annum. In a conduit with a sluggish flow of two miles per hour, there would be silt and deposit of sewage matter, just as in the Mersey and the Dee there were banks of mud owing to the sewage poured into these rivers on both sides. As to the Paris farm near Clichy, it was a chemical swindle, for the sewage was allowed to pass crude into the Seine hard by.

Mr. Isaac Shone was of opinion that the data and calculations of the paper were accurate. Taking the population at 5,500,000, the solid faeces amounted to 384 tons daily, and the fluid to 6,140 tons, or a total of 6,254 daily. The sewage, at 30 gallons per head per diem, amounted to 736,607 tons. Thus the sewage proper was only .82 per cent. of the volume of sewage, which would be represented by one glass of brandy in 99 glasses of water.

Mr. James Lemon said that there was much diversity of opinion among eminent authorities as to the effect of taking the sewage lower down the river. Some thought that it

would not remedy the nuisance, but only alter its locality; others thought that it ought to be subjected to a purifying process before discharge at any point of the river. To carry the sewage of 7,000,000 inhabitants to the sea—for that was the least number to be provided for—was a gigantic operation, and would cost, according to Mr. Baldwin Latham, at least 6,000,000*l.* sterling.

They might purify sewage well on high land, according to his experience; on low land it was difficult to do it. It might at some seasons be effectual, at other times the sewage would all go into the river in its crude state.

Sir Robert Rawlinson, in reply, said that he had not intended to treat the subject from a chemical standpoint, but apologised to Mr. Sillar for his mistake concerning Leamington. It was a mistake to say that "the company were driven" from Leamington. The fact was that the injunction was obtained against the local board of that town, but was suspended for some time to allow the construction of pumping works to remove the sewage to the land. In the year 1869 the A. B. C. Company undertook to deal with the sewage, and did so for a while. The result was set forth in an official report of that date. He also referred to another old report of the Metropolitan Board of Works on experiments made at Crossness in the year 1872 as to the cost of the process. All this, he said, went to show that commercial profit out of sludge was impossible. It ruined two companies at Coventry, although they received 2,000*l.* per annum by way of subsidy.

The Chairman, Sir Henry Roseoe, M.P., F.R.S., in moving a vote of thanks to the author of the paper, said that the subject was of the utmost importance to the nation, and some rational and thorough-going scheme ought to be adopted. Whatever scheme were selected, the work should be done effectually. The question of cost was of much less consequence. If the County Council achieved the work to the satisfaction of the coming generation, they would have earned the thanks of the nation.

Mr. Frank Candy wrote, that Sir R. Rawlinson's estimates were not dated on present prices, but upon data given in 1857! At modern estimates, the annual charge would amount to 300,000*l.*!

He pictured a "new river" of London sewage flowing sluggishly through Essex for 46 miles. Such a river would be in a putrescible condition, and in hot weather would become offensive to the districts through which it passed. With respect to discharging this filth into the estuary of the Thames, what would the towns near the coast have to say? He did not believe in taking the sewage through the marshes for purposes of agriculture. It had failed before—and ignominiously at Liverpool—although the company offered to give the sewage for nothing if the farmers would utilise it.

In this case, if the farmers did not refuse, there was no guarantee that it would be effectively purified, some of it might go crude into streams and watercourses.

Mr. Alfred Roechling wrote, that where London and Paris had failed, Berlin had succeeded. That city was divided into 12 separate drainage systems, called "radial systems," seven being north and five south of the River Spree. Each radial system was entirely independent, and all the sewers radiated from the circumference of the city towards the centre, where the pumping station was situated. Each area averaged about 1,150 acres, with a maximum population of 200,000 in the largest of them. There were storm-overflows connected with the river. The systems lying north of the river pumped their sewage to farms on that side of the city, those on the south to farms on the south side. A total area of 7,900 acres had been specially prepared for irrigation, and more was dealt with every year as the radial systems were completely connected.

The total average of all the farms had now reached 16,477 acres, and the total dry weather flow amounted to 27,000,000 gallons, the water supply only amounting to 14 gallons per head. The population in 1885 was 1,293,920. The farms on the northern side were six miles distant from the heart of the town, those in the south about 12 miles. The health of the labourers on the farms was good, the death rate being

11 per thousand during the last year. The effluent from the northern farms joined the River Spree above Berlin. Sewerage and sewage disposal works had cost 3,943,402*l.* The income from the farms last year was 95,000*l.*, the expenses 86,570*l.*, leaving a surplus of 8,457*l.* in aid of capital and interest. The cost of sewage disposal on the farms was about 10*l.* per head of the population.—C. N. C.

*Improved Apparatus for Preparing Lime and other Substances for the Treatment of Sewage, and for Automatically Supplying them in Measured Quantities thereto.* E. Knowles, Accrington. Eng. Pat. 15,810, November 2, 1888. 8*d.*

THE object of this invention is to reduce, as far as possible, the amount of manual labour in the preparation and application of lime or other substances used in the purification of sewage, and their more equal distribution to the sewage.

Lime is first slaked to a dry "fallen" condition, and then fed into a "pulveriser," a revolving box of such suitable form and having such interior arrangements as to induce a further disintegration of its charge.

The box is provided with a grating or gratings, through which the lime is sifted and delivered in a finely-divided state. It is then lifted, by means of an elevator, into a receiver, from which it is drawn out through an opening at its lower end, by means of a helical rotating "creeper," and is introduced, together with a stream of water, to the "mixer," a vessel fitted with revolving stirrers, and having separate driving gear.

The supply of lime to the mixer is automatically proportioned to the varying quantity of sewage to be dealt with, the quantity of material delivered to the mixer being due to the greater or less velocity of the above-mentioned creeper, or its equivalent. The differential action of the creeper is made to depend on the vertical movements of a float situated in the sewage flow. The float is connected by rods and levers to actuate the creeper, so as to deliver the lime to the mixer in varying proportions due to the quantity of sewage passing.—F. S.

*Improved Method of and Apparatus for the Formation of Organic Oxides, and the Oxidation of Matter Suspended or Dissolved in Liquids.* J. G. Lorrain, London. Eng. Pat. 16,093, November 7, 1888. 6*d.*

OXYGEN, or common air, is blown against the surface of porous carbon immersed in the liquid to be treated, or oxygen is liberated at the surface of the carbon by electrolysis, if such be possible. The carbon absorbing the oxygen facilitates chemical action with the liquid. The invention may be employed in the apparatus described in Eng. Pat. 3826 of 1886 (this Journal, 1887, 377). Freshly prepared "kerosene coke" or ordinary cinders are preferred for the immersed carbon.—E. T.

*Improvements in and connected with the Purification of Sewage and other Foul Liquids.* C. H. Beloe, Westminster. Eng. Pat. 18,568, December 19, 1888. 11*d.*

THE object of the invention is to provide means whereby the deodorising material is automatically mixed in the proper proportions with the liquid under treatment. For this purpose the inventor suspends in the sewer or other channel through which the liquid passes a lever or arm, free to swing therein, and having at the lower end a paddle shaped to correspond with the bottom of the sewer. The upper end of this arm is connected with a cut-off valve, which controls the mouth of a hopper containing the material to be supplied to the liquid. Above this cut off valve is a second valve which regulates the maximum

amount of material which is to be added to the liquid, and below it is a spout to deliver the material into the sewer. When no liquid is flowing the arm hangs vertically, and the mouth of the hopper is closed, but on the flowing of the liquid the arm is deflected and the valve opened. The greater the flow the greater the deflection of the arm, and consequently the greater the amount of material which can pass down from the hopper. Immediately adjoining the spout is a chamber containing a number of baffle-plates or weirs to cause the liquid and the disinfectant to become thoroughly mixed. In another modification the valve is worked by an under-shot water-wheel.—F. S.

*Improved Apparatus for Separating, Filtering, and Disinfecting Fæcal Matters.* J. Chabanel, Marseilles, France. Eng. Pat. 18,791, September 18, 1889. 8d.

THE object of this invention is to secure efficient working of apparatus for separating fæcal matter on the portable tank system, and to enable it to be emptied without stoppage of its working.

The separator is cylindrical in the body, tapering at the bottom to a narrower mouth which fits on to the mouth of a removable tank placed below. The separator contains a perforated cylinder of the same diameter as, and connected with, the mouth of the vessel itself, and the soil pipe opens directly into this cylinder. The mouth can be closed—to enable the tank to be emptied—by a piston which can be raised or lowered, from above, by a screw, the piston being in connexion with a door which closes the mouth of the soil pipe. The tank below is mounted on a table which can be raised or lowered by a screw, and is provided with a cock for drawing off a part of the contents should it be found too full for removal.

A pipe from the separator conveys away the liquid matter, so that if need be the mouth of the soil pipe can be got at for cleaning.

The inside of the cylinder is cleaned by the ascent and descent of the piston.—F. S.

## (C)—DISINFECTANTS.

### PATENTS.

*Process for the Production of Aromatic Dithio-organic Acids.* H. Baum, Frankfort, Germany. Eng. Pat. 14,443, October 8, 1888. 4d.

A SERIES of interesting and more or less important dithio-acids may be prepared by the action of sulphur chloride or bromide upon "oxycarbon acids" of the aromatic series, their formation being thus represented:—

To produce dithio-salicylic acid, for example, 138 kilos. of salicylic acid are heated with 68 kilos. of sulphur chloride ( $\text{S}_2\text{Cl}_2$ ) between  $100^\circ$  and  $150^\circ$  C. until the evolution of  $\text{HCl}$  ceases. The resulting acid is a honey-yellow substance readily soluble in soda without leaving any residue of sulphur. The acid is easily soluble in "benzole" (benzene) and glacial acetic acid, forming when dried and cooled a straw-yellow brittle mass meltable like resin.—O. J. S.

*New or Improved Compositions for Disinfecting, Deodorising or Antiseptic Purposes.* G. R. Tweedie, London. Eng. Pat. 17,042, November 23, 1888. 4d.

THE improved composition consists of a mixture of phenols and terpenes with or without a dry mineral or vegetable powder as vehicles. For example, 1–2 parts of carbolic acid, 4–5 parts oil of turpentine, 1–2 parts of camphor.

These may be simply mixed, or distilled together. As a dry vehicle, powdered alum, borax, kieselsäure, peat, sawdust, moss, &c., may be used.—J. M. H. M.

*Improved Means to be used in the Preservation of Perishable Substances by Fumigation.* G. D. Wheaton, Chicago, U.S.A. Eng. Pat. 18,079, December 11, 1888. 8d.

THE apparatus consists of a chamber divided into two parts. The lower receives the substances to be preserved whilst the upper consists of refrigerating chambers containing flues through which the fumes of the antiseptic compound pass before they can gain access to the substances in the lower part of the chamber. Any suitable antiseptic may be employed, but preference is given to the compounds patented by W. D. Daniels (Eng. Pats. 17,813 of 1888 and 2858 of 1889; this Journal, 1889, 411). Drawings of the apparatus accompany the specification.—E. E. B.

*Improved Means of Effecting the Preservation of Materials of a Perishable Nature, and the Application thereof for Curative Purposes.* G. D. Wheaton, Chicago, U.S.A. Eng. Pat. 771, January 15, 1889. 6d.

THE articles to be preserved are treated with water which has been exposed to the fumes of a mixture of sulphur, sugar, sassafras, cinnamon and potassium nitrate.

If a liquid has to be preserved a portion of it may be subjected to the action of the fumes of the above mixture and then mixed with the remainder of the liquid. The same methods may also be adopted with solid substances, such as butter.—E. E. B.

*An Improved Manufacture or Preparation of Antiseptics.* F. G. A. Roberts, A. Shearer, and W. B. Giles, London. Eng. Pat. 11,974, July 27, 1889. 4d.

DRY salicylic acid is mixed with an anhydrous alkaline sulphite, preferably in about equal parts by weight.

—E. E. B.

*An Improved Disinfecting, Deodorising, and Preserving Compound.* J. G. Fowler and D. Macdonald, Boston, Mass., U.S.A. Eng. Pat. 14,032, September 5, 1889. 4d.

A MIXTURE of boracic acid, 10 parts; salicylic acid, 10 parts; permanganate of potash, 40 parts; and silicate of potash or soda, 40 parts. Ten parts of fresh water sand may be substituted for 10 parts of the alkaline silicate. The mixture forms a hard mass, lumps of which may be placed in water used to supply closets, &c.; it may also be used for washing, preserving meat, &c.—J. M. H. M.

## XIX.—PAPER, PASTEBOARD, Etc.

*Microscopic Examination of Paper.* W. Herzberg. Mitt. Königl. tech. Versuchs. 1889, 3, 113–115.

See under XXIII., page 112.

*Contributions to the Knowledge of the Sizing of Paper.* W. Herzberg. Mitt. Königl. tech. Versuchs. 1889, 3, 107–113.

(A.) *Action of Light on Rosin Sizing.*—It was observed that the label of a laboratory book which had been begun to be used in 1884, and was then quite free from any tendency to make the ink "run," had completely lost this property when the date on which it was filled was inserted in 1887, proving that some alteration had taken place in its sizing. Five kinds of paper were therefore exposed between double windows to direct sunshine and air for two periods of two

months each, and tested at the end of each period as to the permanence of their sizing. They had been proved normal in this respect at the beginning of the experiment, both by their ability to bear writing upon without running, and by Leonardi's test (see below). At the end of the second period of two months, four out of the five kinds (which comprised paper from linen and cotton rags with and without wood and straw cellulose) were no longer fit for writing upon, while the fifth, made of a mixture of wood pulp and wood cellulose and containing 13.5 per cent. of ash, was almost unaffected, although its colour was most altered, having changed to a well-marked brown tint. That this effect of exposure to air and sunshine on the rosin used in sizing the papers was due to the action of light, and not to that of oxygen or carbon dioxide, was shown by experiments in which the papers were enclosed in vessels filled with these gases and kept in diffused daylight without suffering change.

The exact nature of the alteration in rosin brought about by the action of light is difficult to determine. A piece of rosin exposed to sunshine loses its vitreous appearance and becomes covered with a yellow powder; a similar change in the rosin on the paper would cause it to lose its impermeability. The reason for this change in the rosin may be the loss of certain volatile constituents followed by crystallisation of the residue, in a manner analogous to the alteration of barley sugar from the vitreous to the crystalline state consequent on the volatilisation of the small quality of water it originally contained.

(B.) *Characteristic Difference of Animal and Rosin Sizing.*—A paper sized with rosin, when extracted with absolute alcohol gives a solution which, poured into excess of water, yields a milky turbidity due to precipitated rosin. Another test is based on the Raspail reaction, rosin giving with sugar solution and sulphuric acid, a violet-red colour similar to that produced by albuminoids. The sugar may be omitted as enough is formed for the reaction by the action of the sulphuric acid on the cellulose of the paper.

The presence of animal size is detected by treating the aqueous extract of the paper with tannin. The following fundamental distinction between papers sized with rosin and gelatin is found to exist. In the former the rosin is distributed uniformly throughout the substance of the paper, while in the latter, whether the sizing has been performed in the pulp or sheet, it is always found exclusively on the surface of the finished product. This peculiar property of gelatin can be shown by saturating a plaster of Paris slab with gelatin solution coloured suitably, and breaking it when dry, on which it will be found to be coloured to a trifling depth, the inner part being white. On these facts this test is based:—A half-sheet of paper is repeatedly crumpled and unfolded, and when the surface has been thoroughly chafed is smoothed out and written upon; if it is sized with rosin the inscribed characters are but little blurred, while if animal size has been used they run freely and are visible from the opposite side of the sheet. Leonardi has modified this test, removing the doubtful element introduced by the manual use of pen and ink. A pipette of which the exit is 10 cm. above the paper, and which delivers drops weighing 0.03 grm. each, is filled with a solution of ferric chloride containing 1.531 per cent. of iron. A single drop is allowed to fall and to remain on the paper for the same number of seconds that 1 sq. m. of the paper weighs in grammes, when it is removed by blotting paper, and the under side of the paper dabbed with a plug of wadding wet with a weak solution of tannin; the production of a black colour proves the iron solution to have penetrated, and therefore shows the sizing to be of animal origin, while in the contrary case the presence of rosin is demonstrated.—B. B.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Physiological Action of Sulphones.* E. Baumann and A. Kast. *Zeits. f. physiol. Chem.* 1889, **15**, 52.

EXPERIMENTS on the physiological action of sulphones and disulphones showed a distinct connexion between constitution, on the one hand, and action on the system, with corresponding decomposition of the substance, on the other hand. It was thought desirable to ascertain in how far the action of sulphonol corresponded with the action of similarly constituted bodies; whether any influence was exerted by the sulphonic group, or by the ethyl, or methyl groups; and, finally, what differences manifest themselves in disulphones by substituting ethyl groups for methyl in the sulphonic groups. Disulphones, in which the sulphonic groups are attached to different carbon atoms, were not considered; the action of those only was considered in which the sulphonic groups are both attached to one and the same carbon atom. Such disulphones are divisible into three distinct classes—

- (1)  $\text{CH}_2(\text{SO}_2\text{R})_2$  ..... methylene disulphones.
- (2)  $\text{CH}.\text{R}'(\text{SO}_2\text{R})_2$  ..... methenyl disulphones.
- (3)  $\text{CR}'\text{R}''(\text{SO}_2\text{R})_2$  ..... ketone disulphones.

The experiments show that diethyl sulphone, the methylene disulphones, and ethylenediethyl sulphone pass through the system undecomposed, and consequently these bodies exert no action on the system. The methenyl disulphones—

are for the most part decomposed in the system, but the ketone disulphones—

are so completely transformed that traces of the same may only be detected in the urine after administration of considerable doses. It would thus seem that in the system the ketone disulphones are the most easily decomposed of all. At the same time they resist the action of alkalis, strong acids, and oxidising agents, as sulphonol itself does, more than the other disulphones. And in physiological action, just as in chemical character, the methenyl disulphones rank themselves between the other two classes. The experiments show, moreover, that only such disulphones are active as contain ethyl groups, and the intensity of such action is dependent on the number of ethyl groups. The group  $\text{SO}_2$ , as such, exerts no action; the group  $\text{SO}_2\text{C}_2\text{H}_5$  is equivalent to an ethyl group combined with the same carbon atom. The authors are thus led to consider that the sulphur has only an indirect action on the system in so far as a stable compound containing two ethyl residues is thereby obtained. Owing to this is doubtless due the limited action of sulphonol on the system; and this may serve to explain why fatalities by excessive doses of sulphonol have not occurred.—T. L. B.

*Synthesis of Pyridine and Piperidine Bases containing Oxygen.* A. Ladenburg. *Ber.* **22**, 2583—2590.

REFERRING to previous investigations on the subject, the author states that he obtained remarkable results by means of the three following reactions:—(1) Substituting alkyl radicles in the pyridine nucleus, by heating pyridine bases with alkyl-iodides. (2) Converting pyridine bases into the corresponding piperidine bases by means of sodimi and absolute alcohol. (3) Forming condensation products by acting with aldehydes upon substituted pyridine bases, and thereby forming unsaturated compounds.

For the last two years the author tried to find a method of preparing pyridine bases containing oxygen, and has at

last succeeded, by forming direct addition products from a substituted pyridine bases and aldehydes, without elimination of water. He describes the bodies thus obtained as "alkines," and has prepared the following compounds: *α-picolylalkine*,  $C_5H_7NCH_2CH_2OH$ , boiling at  $179^\circ C$ , under 25 mm. pressure, and forming a colourless syrup. On treating this base with potash or concentrated sulphuric acid, vinyl-pyridine,  $C_5H_4NC_2H_3$ , is obtained. *α-pipecolylalkine*,  $C_5H_9(CH_2 \cdot CH_2OH)NH$  (the expression "pipe" being used as an abbreviation for the radical of piperidine). By methylating this body, methylpipecolinalkine is obtained, which is of some interest, as it only contains two hydrogen atoms more than tropine. He also prepared *α-pipecolylmethylalkine*,  $C_5H_9(CH_2 \cdot CH_2OHCH_3)NH$ , which body stands in close relation with Wertheim's *conydrin*.—O. J. S.

*Cinnamylcocaine*. C. Liebermann. Ber. 22, 2661—2662.

The cinnamylcocaine found by Giesel (this Journal, 1889, 1004), as predicted by the author, in the amorphous bases accompanying cocaine, has been further examined by the latter. As Giesel has proved the identity of the natural base with that synthesised by the author as far as regards the following properties, melting point, appearance, solubility, and behaviour on decomposition, there only remained the careful examination of the crystalline form to definitely establish the identity. The crystalline form of cinnamylcocaine obtained from coca leaves is now found to be precisely the same as that of the artificial product.—E. B.

*On the Etheral Oil of Betel Leaves*. J. F. Eykman. Ber. 22, 2736—2754.

The author prepared, in 1885, betel oil from freshly gathered leaves of *Charicia Belle Miq.* = *Piper Belle L.* of the botanical gardens in Buitenzorg (Java). This oil is a slightly greenish-yellow coloured liquid of an aromatic taste and smell, which turns brown on being exposed to the action of air, and at the same time acquires a burning taste. The oil is slightly levo-rotatory ( $-3.5^\circ$  pro 2 dm. layer in sodium light), and has a specific gravity of 0.959 at  $27^\circ$ . The author has succeeded in isolating three chief components from this oil, citreneterpene, a sesqui-terpene, and para-allylphenol (*Charicol*).—

whereas, according to a report of Schimmel and Co., in Leipzig, betel oil contains chiefly eugenol and a hydrocarbon boiling at  $260^\circ$ . In a later publication, however, on this subject by the above firm, betel oil was found not to contain eugenol, but an isomeric body—

(Bertram and Gildemeister, this Journal, 1889, 816), which they named "betelphenol." The phenolic body charicol, which was isolated from the oil by means of KOH and precipitation with dilute acid, boils at  $237^\circ$ , and forms a colourless clear liquid of characteristic taste and smell, and has a specific gravity of 1.041 at  $13^\circ$ . According to the author, charicol possesses a far greater antiseptic power than either phenol or eugenol, being about five times stronger than phenol and twice as strong as eugenol. The hydrocarbons isolated from the oil boiled between  $173^\circ$ — $190^\circ$  and  $190^\circ$ — $220^\circ$ , did not yield a pure terpene of a constant boiling point, but probably contained cymol and cineol, &c., but no pinene. The lower boiling portion of citrene, with a decided smell, had a specific gravity of 0.848 at  $16^\circ$  and a rotatory power of  $-5.20^\circ$ . The other part had a greater rotatory power, and probably contains menthol. The author concludes, after carefully comparing this oil with the oil from Schimmel and Co., that they are distinctly different, and as the latter does not contain the lower boiling bodies, they can hardly claim the name betel oil for their product.—O. J. S.

*On the Chemical Constitution of Safrol*. T. Poleck. Ber. 22, 2861—2863.

In order to substantiate the formula of safrol, which was supposed to be allyldioxybenzene,  $C_6H_6(O_2CH_2)_2C_3H_5$ , this body was oxidised with a 4 per cent. solution of potassium permanganate. The products obtained, however, were piperonal, piperonic acid, carbonic acid, formic, acetic and oxalic acid, but no propionic acid. Under these circumstances the present formula of safrol can be maintained no longer.—O. J. S.

*On Hydrocarbon in the Etheral Oil of Carlina Acaulis L.* F. W. Semmler. Chem. Zeit. 13, 1158.

The etheral oil of the earline thistle, which is dark reddish brown with the characteristic narcotic odour of wurzel, sp. gr. 1.026 at  $21.9^\circ$ , boiling point  $265^\circ$ — $300^\circ$ , gave on ultimate analysis C, 85.89; H, 6.75; O, 7.36. By distilling in vacuo a clear yellow fraction distilling at  $155^\circ$  was obtained, of which the ultimate analysis was C, 87.42; H, 10.84. This fraction redistilled in vacuo over metallic sodium gave a colourless distillate of elementary composition C, 88.21; H, 11.74. Thus undoubtedly a hydrocarbon is obtained: the formula  $(C_5H_8)_n$  corresponds to the terpene series. The boiling point at the ordinary pressure is  $250^\circ$ — $253^\circ$ . From the crude oil 12 per cent. of this hydrocarbon can be obtained. The author is engaged on research of further bodies in this oil.—D. A. S.

*Action of Dilute Acids on Benzoylsulphonic-imide and the Analysis of Commercial Saccharine*. I. Rensen and W. M. Burton. Amer. Chem. Jour. 11, 403—408.

When benzoylsulphonic-imide is boiled with hydrochloric acid it is first converted into orthosulphamiebenzoic acid, but on continued boiling it is completely converted into hydrogen ammonium orthosulphobenzoate; the changes which take place are probably represented by the equations—

A number of experiments showed that this change is brought about most quickly (in 8—10 minutes) by an acid prepared by diluting pure hydrochloric acid of sp. gr. 1.17 with 8—10 parts of water. The concentrated acid has only a slow action at  $100^\circ$ , but at  $150^\circ$  the change takes place rapidly. The end of the reaction can be readily ascertained by tasting the solution, the quantity of the orthosulphamiebenzoic acid present being insignificant.

The easy conversion of benzoylsulphonic-imide into a substance which is readily soluble in water suggests a method for determining this constituent of saccharine.

The commercial article contains at least three substances, namely, benzoylsulphonic-imide, parasulphamiebenzoic acid, and potassium hydrogen orthosulphobenzoate, possibly also some unoxidised sulphoniamides. When commercial saccharine is boiled with excess of dilute (1:8) hydrochloric acid the sulphimide is converted into ammonium hydrogen orthosulphobenzoate, whilst the other compounds remain unchanged.

If the solution is concentrated and allowed to cool, the parasulphamiebenzoic acid, which is very sparingly soluble in cold water, crystallises from the solution (quite free from any ortho-acid) and, on filtering, the potassium and ammonium salts of the orthosulphobenzoic acid will be present in the filtrate. The combined weight of these salts can be determined by evaporating to dryness, and the quantity of potassium salt in the residue can be ascertained by estimating the quantity of potassium.

The difference between the combined weight and that of the potassium hydrogen orthosulphobenzoate alone gives the weight of the ammonium hydrogen orthosulphobenzoate, and consequently that of the original benzoylsulphonic-imide. No potassium salt, other than that of orthosulphobenzoic acid, was detected in experiments with commercial saccharine.

The most convenient method for the analysis of saccharine was found to be the following:—About 2 grms. of saccharine are boiled for an hour with 100 cc. of hydrochloric acid (1:8) in a flask of 250 cc. capacity provided with a reflux condenser. The clear solution is then concentrated to 15 cc. in a dish, allowed to stand for several hours, the crystals of the parasulphonic acid collected on a weighed filter, washed with cold water, dried at 80° and weighed. The filtrate and washings are evaporated to dryness, weighed, and the potassium in the residue determined by treating a weighed portion with sulphuric acid.

The results of five parallel analyses of two samples of saccharine are given below (in percentages):—

SAMPLE I.

—	I.	II.	III.	IV.	V.
Parasulphamiebenzoic acid..	49.20	50.36	48.70	51.01	50.75
Benzoylsulphonic-imide .....	32.12	32.71	33.19	33.80	32.18
Potassium hydrogen sulpho- benzoate.....	7.20	6.94	7.21	7.22	7.12

SAMPLE II.

—	I.	II.	III.	IV.	V.
Parasulphamiebenzoic acid..	43.79	45.13	45.26	43.48	44.78
Benzoylsulphonic-imide .....	48.65	48.29	47.95	48.22	48.53
Potassium hydrogen sulpho- benzoate.....	8.10	7.98	7.90	7.99	7.99

These analyses show that the quantity of benzoylsulphonic-imide in commercial saccharine is somewhat less than 50 per cent., so that the commercial article has a sweetening power about 125 times as great as that of cane sugar.—E. S. K.

#### A New Iodoform Industry. S. Casthélaz, Bruère, and Co. Rép. de Pharm. 45, 481.

Iodoform is prepared from Varce soda by Suilliot and Reynaud's process (see this Journal 1889, 210) at the manufactory of S. Casthélaz, Bruère, and Co., at la Poterie-de-Belbeuf, near Rouen. The alkaline iodides are extracted from the Varce soda by systematic washing with cold water, or by means of steam extraction, aided by a mechanical stirring apparatus. The solution obtained is desulphurised by known methods and filtered. The clear filtrate is mixed in a large vat, provided with stirring apparatus, with sodium hydrate, acetone, and sodium hypochlorite. The iodoform which separates is purified in the usual way. The mother-liquor from these operations is worked up, first for potassium sulphate and chloride, and then for bromine.—H. T. P.

#### Action of Hydrocyanic Acid on Calomel. Fouquet. J. Pharm. Chim. 1889, 397.

THE gray colour caused by the action of hydrocyanic acid on calomel has long been known. *Scheel* gives the reaction:  $2 \text{HgCl} + 2 \text{HCN} = \text{Hg} + \text{Hg}(\text{CN})_2 + 2 \text{HCl}$ . *Bussy* and *Buquet* treated 1 gm. of calomel repeatedly with hydrocyanic acid (1:10) and obtained 0.42 gm. of mercury and 0.56 gm. of mercuric chloride, and concluded that the hydrocyanic acid simply decomposed the calomel into mercury and mercuric chloride. As, however, this ran counter to thermo-chemical considerations, the author repeated their experiments and obtained the same quantity of mercury left, but on examining the filtrate found that it was not a solution of mercuric chloride mixed with hydrocyanic acid, but one of mercuric cyanide in hydrochloric acid, for it was strongly acid in reaction, gave no precipitate with potash, and if first neutralised none with

potassium iodide. On evaporating, mercuric chloride was certainly left, due to the expulsion of hydrocyanic acid by hydrochloric acid as concentration proceeded. It, therefore, appears that the reaction occurs in the manner indicated by *Scheel*, but it is never complete by a single treatment with hydrocyanic acid, for it ceases directly the proportion of hydrochloric acid present rises to a certain limit. It can be aided by neutralising the acid as it forms, and hindered by the addition of an initial dose of acid. Pharmaceutical preparations containing hydrocyanic acid and calomel, though apt to become discoloured from this reaction, are not more dangerous on account of the mercuric cyanide formed than they are from the corresponding quantity of hydrocyanic acid originally present.

—B. B.

#### Ouabaïo—The Poison of the Somalis. Cathelineau. J. Pharm. Chim. 1889, 436.

ALONG the whole of the west coast of Africa, especially in the country of the Somalis, occurs a tree used by the natives for the preparation of their arrow-poison, and called by them Ouabaïo. Its wood is yellowish white, very hard and dense, odourless, but possessing a strong bitter taste. *Arnaud* has isolated from it (this Journal, 1889, 211; 1888, 586) Ouabaïo,  $\text{C}_{30}\text{H}_{40}\text{O}_{12}$ , which has a physiological action similar to that of strophanthin,  $\text{C}_{31}\text{H}_{45}\text{O}_{12}$ , but which is twice as toxic, the poisonous dose being about 0.2 mgrm. per kilo. of body-weight (this Journal, 1888, 765).—B. B.

#### Sommal. E. Ritsert. Pharm. Zeit. 1889, 674.

RADLAUER has patented and brought upon the market a soporific to which he assigns the formula—

and the name *Sommal*. He prepares it by heating a mixture of equal parts of chloral hydrate, urethane and alcohol to 100° C. The author disputes the possibility of such a mode of preparation; there is no evidence of any reaction occurring when these bodies are mixed cold, no chloral ethylate is formed at 100° C., and chloral urethane is decomposed at 100° C. Although chloral hydrate will give no reaction under these conditions, chloral will, and one obtains chloral alcoholate or chloral urethane according to the order of addition of the reacting substances, the product being in one case unattacked by the subsequent addition of alcohol, and in the other of urethane. "*Sommal*" is therefore nothing but a mixture of chloral hydrate, urethane and alcohol.

—B. B.

#### PATENTS.

##### Improvements in the Preservation of Peroxide of Hydrogen. C. T. Kingzett, London. Eng. Pat. 15,993, November 5, 1888. 4d.

A SMALL quantity, say 1 per cent. of either of the following substances, is added to the solution of hydrogen peroxide: alcohol, acetic acid, chloral, chloroform, or glycerin, alcohol being preferred.—J. M. H. M.

##### Apparatus for the Production of Ozone. E. Fahrig and H. E. Billing, London. Eng. Pat. 16,139, November 7, 1888. 6d.

THIS invention relates to the production of ozone by subjecting air to electrical action in the following manner:—By means of a pump, blower, or fan a current of dry and purified air is passed in thin layers between a number of corrugated plates. "Each plate is made of non-conducting material coated on one surface with metal foil, and is connected to one of the terminals of the secondary coil of an inductor, the next plate in order being connected to the other terminals of a dynamo-electric machine producing alternating currents."—O. J. S.

*Improvements in Dental Anodynes or Obtundents.* R. I. Hunter, Norfolk, U.S.A. Eng. Pat. 17,627, December 3, 1888. 4d.

THE compound consists of an aqueous solution containing chloral, cocaine, arsenic, creosote, and carbolic acid.  
—E. E. B.

*The Manufacture of a Substitute for Musk.* E. Schnauffer and H. Hupfeld, Frankfort, Germany. Eng. Pat. 18,521, December 18, 1888. 4d.

THIS invention relates to the manufacture of a substitute for musk. Aromatic hydrocarbons such as benzene, toluene, or xylene, are converted into isopropyl, isobutyl, or isoamyl derivatives and then nitrated, and the products of this reaction are poured into water, whereupon a reddish-brown oil separates out, which is washed several times in alkaline water. For instance, if metaxylene be heated with isabenzylalcohol and chloride of zinc under pressure, and the resulting dimethylisopropylbenzene subsequently treated with nitric acid, an oil,  $C_{12}H_{17}NO_2$ , is obtained, which, in a concentrated condition possesses a sweet smell, whilst in a dilute alcoholic solution it gives off a penetrating and enduring musk-like odour.—O. J. S.

*Improved Apparatus for Percolating and Expressing Tinctures, Fluid Extracts, or Concentrated Infusions.* F. Tebbutt, London. Eng. Pat. 486, January 10, 1889. 6d.

THE apparatus consists of a cylindrical vessel, having a perforated false bottom and provided with a "screw or press" by means of which the ingredients to be treated may be compressed between this false bottom and a perforated plate.—O. H.

## XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

*Development with Quinol.* E. Himly. Phot. Correspondenz, 26, 152—159.

POTASSIUM metasilphite preserves the quinol solution better than sodium sulphite alone, but it is not advisable to reduce the quantity of the latter since it exerts a beneficial effect on the colour of the image. Four parts of quinol in 1,000 is the smallest quantity which can be used with good results. The addition of 2 to 3 per cent. by volume of a solution of sodium hydroxide (1:8) to the ordinary solution of quinol and an alkaline carbonate reduces the time required for development, and gives a considerable increase in the amount of detail in the image, and a more brilliant negative generally. It is also an advantage when developing positive images on glass or paper. Potassium metasilphite acts as a restrainer of considerable power when used with either quinol or pyrogallol, and in the latter case the addition of a small quantity of the dilute sodium hydroxide solution to the ordinary developer containing sodium or potassium carbonate is a distinct improvement. In all cases the time required for the first appearance of the image and for the completion of development was considerably less with pyrogallol than with quinol.

Solutions recommended are as follows:—

A. Quinol, 10 parts; potassium metasilphite, 4 parts; water, 250 parts.

B. Sodium or potassium carbonate, 10 parts; sodium sulphite, 5 parts; water, 100 parts.

Mix 10 parts of A with 50 to 75 parts of B and 25 to 50 parts of water.

The quinol solution may contain 25 to 50 parts of sodium sulphite, with or without the potassium metasilphite. Instead of the alkaline carbonate solution, 10 parts of the quinol solution may be mixed with 100 parts of water and 10 parts of a solution (C) sodium hydroxide, 5 parts; sodium sulphite, 5 parts, and water 40 parts.—C. H. B.

*Development with Quinol containing Potassium Ferrocyanide.* E. Himly. Phot. Correspondenz, 26, 160—162.

THE addition of potassium ferrocyanide to the quinol developer gives a greater amount of detail with increased contrast in the image, and at the same time reduces the time required for development. The use of potassium bromide is not necessary unless the film has a tendency to fog. The ferrocyanide is best kept in the form of a 30 per cent. solution, which is added in drops as occasion requires.

—C. H. B.

*Gelatinobromide Emulsion prepared with Ammonio-Silver Nitrate.* J. M. Eder. Phot. Correspondenz, 26, 169—171.

TWENTY-FOUR grms. potassium bromide and 25 grms. of Winterthur's gelatin are dissolved in 230 cc. of water in the usual manner, with or without the addition of 8 cc. of a 10 per cent. solution of potassium iodide. Three grms. of citric acid are dissolved in 230 cc. of water, mixed with 30 grms. of silver nitrate, and then ammonia is added until the liquid just becomes clear. Both solutions are heated to 50°, carefully mixed with vigorous agitation, and then heated for 45 minutes in a water-bath at 40° to 45°, or, if greater sensitiveness is required, at 50°. Fifteen grms. of gelatin previously swelled in cold water and melted is added, and the other operations are conducted in the usual manner. The filtered emulsion, before coating the plates, should be mixed with 1 per cent. by volume of a 2 per cent. solution of chromic alum.

The plates prepared in this manner are of moderate sensitiveness, but are free from tendency to fog, and give images of good quality. They are especially suitable for landscape work, and for micro-photography. Greater sensitiveness can be obtained by digesting the emulsion at 60° to 70°, but the quality of the plate is by no means so good.—C. H. B.

*The Acid Fixing Bath.* A. Lainer. Phot. Correspondenz, 26, 273—274.

THE acid fixing bath (this Journal, 1889, 637) is not only advantageous with all alkaline developers on account of its power of removing stains, but also because it exerts a distinct toughening and contractile influence on the gelatin film and thereby reduces the risk of frilling.—C. H. B.

*Development with Catechol and with Paraphenylenediamine.* J. M. Eder. Phot. Correspondenz, 26, 309—311.

*Catechol.*—One part of catechol and 4 parts of sodium sulphite were dissolved in 40 parts of water, and mixed with twice its volume of a solution of 2 parts potassium carbonate in 40 parts of water. Sodium sulphite keeps the solution clear, although it somewhat retards development. Development proceeds much more quickly than with a quinol developer of corresponding composition. Even when dilute to one-third of the strength given, the developing power remained considerable.

*Paraphenylenediamine* gives about the same degree of sensitiveness as pyrogallol or quinol. Development is regular, and the image is grey and soft. A 2 per cent. solution of *p*-phenylenediamine hydrochloride was mixed with 1 to 2 vols. of a 10 per cent. solution of potassium carbonate. Sodium sulphite acts as a very powerful restrainer of development.—C. H. B.

*Development with "Eikonogen."* J. M. Eder. Phot. Correspondenz, 26, 519—521.

"EIKONOGEN" is the sodium salt of amido- $\beta$ -naphthol- $\beta$ -monosulphonic acid. When mixed with alkalis it develops gelatinobromide plates successfully, giving soft and well-graduated images, free from fog. It is best to keep the eikonogen and the alkali in separate solutions. For ordinary purposes the following solutions may be used:—(A.) 50 grms. of Eikonogen dissolved in a solution of 200 grms. of sodium sulphite in 3,000 cc. of water. (B.) 150 grms. of crystallised sodium carbonate in 1,000 cc. of water.

Three parts of A are mixed with 1 part of B, potassium bromide being added if a restrainer be needed. For brief exposures 5 grms. of potassium carbonate and 10 grms. of sodium sulphite are dissolved in 150 cc. of water, to which are added 5 grms. of Eikonogen.—C. H. B.

*Deterioration of Gelatinobromide Plates.* E. Vogel. Phot. Mittheilungen, **26**, 9—11 and 126—128.

THE black rims which appear on the development of dry plates which have been kept for some time are due to the use of impure packing paper. In order to test the latter it may be boiled with water, and the solution mixed with a few drops of silver nitrate solution and again boiled, when a brown or black precipitate of silver sulphide will be formed. The original solution may be mixed with starch paste and iodine solution, when it will be found that several drops of the iodine solution are required to produce a blue colouration. Neither of these tests always give satisfactory results, and it is better to enclose a piece of the paper between a sensitive film and a sheet of perfectly clean glass in an ordinary printing frame in the dark room for about a week, and then develop the sensitive film as if it had been exposed to light. The following results were obtained:—*strongly-marked action*, common black paper, glazed common black paper, smooth black paper, ordinary note-paper; *weak action*, ordinary photographic paper, smooth yellow packing paper, filter paper; *no action*, Swedish filter paper, tissue paper, and tissue paper soaked in paraffin. The effect seems to be due to the evolution of some reducing gases from the paper, for it is not prevented by the insertion of porous pure paper between the impure paper and the sensitive film.—C. H. B.

*Gelatinobromide Plates with fine Grain.* O. Lohse. Phot. Mittheilungen, **26**, 25—26.

SILVER bromide is appreciably soluble in gelatin solution, forming an opalescent solution which is reddish by transmitted light and forms an almost perfectly transparent layer if allowed to dry upon glass. In contact with ammonia vapour the silver bromide separates in a granular form, and in both this and the ordinary process of making the emulsion, the fineness of the grain depends on the duration of the time of action of the ammonia. An emulsion with a very fine grain, of comparatively low sensitiveness, but especially suitable for micro-photography and similar purposes, can be obtained in the following manner:—Two solutions are prepared (A) by dissolving 2 grms. of gelatin in a small quantity of water at the lowest possible temperature, and then adding 1 gm. of silver nitrate dissolved in a small quantity of water, the total bulk of liquid being 50 cc.; and (B) by dissolving 2 grms. of gelatin and 0.6 gm. of ammonium bromide in 50 cc. of water. The two solutions are mixed whilst warm, and, after vigorous agitation, poured into 200 cc. of alcohol. The precipitate is washed with cold water until all soluble salts are removed, melted at a low temperature, and diluted to 100 cc. Plates are then coated with it in the ordinary manner, and, after being dried, are immersed in a mixture of equal parts of absolute alcohol and water, exposed to the action of ammonia vapour for not more than a minute, and again dried.—C. H. B.

*Sodium Bichromate in Photo-mechanical Printing Processes.* J. Husnik. Phot. Mittheilungen, **26**, 238.

SODIUM bichromate can be used in photo-mechanical processes for all purposes for which the potassium salt has hitherto been employed. It is much cheaper, can be used in much more concentrated solutions, and has not the same tendency to crystallise in the films. It has a lower molecular weight, but since it always contains water, there is no need to make any alteration in the weight of bichromate given in the usual formulae.—C. H. B.

*Orthochromatic Photography with Gelatin Plates.* C. H. Bothamley. Phot. News, **33**, 563—565.

IT is well established that a higher sensitiveness to the less refrangible rays is obtained by treating ordinary gelatinobromide plates with an ammoniacal solution of an Eosin dye or Cyanin than by adding these substances to the melted emulsion or to the materials before emulsifying, although in the first case the plates are more liable to deteriorate if kept for some time before being used. In order to ascertain the best method of working the bath process the author has examined the various modifications which have been proposed, the special points investigated being the necessity or advantage of a preliminary bath of dilute ammonia, of adding alcohol to the sensitising bath, and of washing the plate after treatment with the dye solution. The sensitiveness of the plates to the less refrangible rays was determined by the method previously described (this Journal, **7**, 767). All experiments were made in duplicate with plates prepared by different methods, and the results are given in the form of tables. The selective sensitiser (*loc. cit.*) employed was Erythrosin, and the conclusions arrived at are:—(1) Alcohol up to 10 per cent. has no influence whatever and may be dispensed with in all cases where the dye is soluble in water; alcohol in larger proportion produces a distinct decrease in sensitiveness. (2) With a concentration of the dye solution not exceeding 1 in 5,000 the washing of the plate after immersion in the bath is unnecessary. (3) A preliminary bath of dilute ammonia is also unnecessary. With the particular plates used no increase of sensitiveness was gained by increasing the concentration of the dye from 1 in 10,000 to 1 in 5,000, but if the plates have been prepared with hard gelatin or have been treated with chrome alum it is advisable to use the stronger bath or to increase the time of immersion. Ives floods ordinary dry plates with an alcoholic solution of the dye (1 in 1,750), allows the alcohol to evaporate, and then washes with water; but it was not easy to see why this method should give results different from those obtained by simple immersion in a dilute aqueous solution of the dye, and photometric measurements confirm this supposition. The author was unable to obtain satisfactory results by using Cyanin in this manner.

The best results, as regards sensitiveness to the less refrangible rays, are obtained in the following simple manner: Dust the plate, and immerse it for two or three minutes in a solution containing—

	Parts.
Dye solution (1:1,000).....	1 to 2
Ammonia (1:10) .....	1
Water.....	up to 10

Allow the plate to drain for some time, place the lower edge on filter paper, to remove the ridge of liquid which collects there, and dry in a pure atmosphere in the dark.

Some experiments on the sensitising action of rhodamin were made in a similar manner. The sensitising effect for the less refrangible rays varies considerably, according to the manner in which the original plates were prepared, but is always less than that of Erythrosin.

The results of a series of experiments on the use of orthochromatic plates for landscape work are also described, and the considerations involved in the use of a transparent yellow screen to reduce the intensity of the blue and violet rays are discussed.—C. H. B.

*The Substitution of Gelatin for Collodion in Photography.* J. Franklin Inst. **98**, 233, 234.

THE Committee on Science and the Arts of the Franklin Institute has awarded the "John Scott Legney Premium and Medal" to Dr. Maddox for his invention of the gelatinobromide process as published by him in the *British Journal of Photography*, September 8, 1871, in the following terms: "Originally thirty grains of gelatin were swelled in cold water, then dissolved by heat, four drachms of pure water and two drops of aqua regia being added. To this solution eight grains of cadmium bromide and fifteen grains of silver nitrate were added, forming a fine milky emulsion of silver bromide. Without further treatment this was spread upon glass plates and dried. The plates were tested by

exposing them beneath negatives and gave a faint but clear image when developed with a plain solution of pyrogallie acid: intensification with pyro and nitrate of silver followed.

\* \* \* So far as can be judged, the process seems worth more carefully conducted experiments, and if found advantageous, adds another handle to the photographer's wheel."—B. B.

*Formic Aldehyde and its Compounds applied to Photography.* J. Schnauss. Chem. Zeit. 13, 1633.

THE well-known property of the aldehydes to reduce silver to the metallic state from an ammoniacal solution of silver nitrate, especially when warmed, suggests their application to photography. But their use has heretofore been impractical owing to their strong odour, their insolubility or difficult solubility in water, and the facility with which they oxidise on exposure to the air. The aldehydes, however, and in particular formic aldehyde, form easily soluble compounds with the alkaline bisulphites, and these salts may be used with advantage, in many ways, in photography. A process in which they are employed has been patented by Schwartz and Mercklin.

Sodium oxymethyl sulphonate (formic aldehyde sodium bisulphite) is valuable (particularly in conjunction with an alkaline carbonate) both as an addition to ripening gelatin-emulsion—the ripening of which it accelerates, imparting vigour and clearness to the negative—and as an addition to the developer, be it ferrous oxalate, pyrogallol, or quinol (hydroquinone), it which case it acts not only as a preservative, owing to its affinity for oxygen, but also as an accelerator, and preventer of "veiling" or "fog."

These compounds have the same kind of effect although in less degree, when they are used in very dilute solution, together with a carbonate of the alkali or of ammonium, as a bath for exposed plates before developing.

If finished dry plates be plunged in a bath of the alkaline solution of the aldehyde salt, and then dried and exposed, results are obtained similar to those produced by adding the aldehyde salt to the emulsion before ripening.

The action of formic aldehyde (and its compounds) depends no doubt upon the energy with which it absorbs or acts as a transferer of bromine and iodine. This property can be demonstrated as follows:—When a solution of iodine is partially precipitated with silver nitrate, the precipitate is of a brown or grey colour owing to the retention of free iodine; but if formic aldehyde be previously added the precipitate will be of a pure yellow-white colour. Again, when caustic magnesia is treated with iodine solution, no decolouration takes place unless upon long standing, but on adding formic aldehyde the colour of the iodine is at once discharged and magnesium iodide goes into solution.

The oxymethyl sulphonates, e.g., the sodium or the silver salt, show an even greater activity as absorbents of bromine and iodine. The sodium salt decomposes silver bromide forming silver oxymethyl sulphonate, silver sulphite, sodium bromide, and formic aldehyde. When finished dry plates are treated with a solution of the sodium salt, the small quantity of formic aldehyde that is formed does not all volatilise on drying, but a portion of it remains in the film as fixed paraformaldehyde, possessing the same photochemical properties as the volatile aldehyde. Possibly also when formic aldehyde salts act on silver bromide in an alkaline solution bromoform is formed, the free formic and hydrobromic acids being taken up by the alkali of the bath, tending to the production of clearness in the pictures.

—H. S. P.

#### PATENTS.

*Improvements in Colour Photography.* A. H. Cros, Paris, France. Eng. Pat. 9012, November 8, 1888. 8d.

AN apparatus for obtaining simultaneously three negatives of an object by means of the rays which have passed respectively through orange, green, and violet glass. These negatives are intended for use in the Cros method of producing coloured pictures by photography. The apparatus, of which drawings are given, consists of three cameras placed side by side and enclosed in a larger camera. Each

of the internal cameras is provided with a plate holder and a coloured glass screen. One lens only is used, and inside the larger camera is a rotating disc with transparent sectors and opaque reflecting sectors, so arranged in conjunction with a plane mirror that when the disc is rotated the rays from the lens are admitted to the three cameras in rapid alternation.—C. H. B.

*Improvements in the Production of Films Sensitive to Light and of Materials for Assisting or Continuing the Effect of Light on Photographic Films.* A. F. Y. Schwarz and F. H. Mercklin, Hanover, Germany. Eng. Pat. 741, January 15, 1889. 6d.

FORMALDEHYDE, paraformaldehyde, or the compounds of formaldehyde with the acid sulphites of the alkalis, silver or iron are added to the gelatinobromide emulsion either just before coating or before ripening, in the proportion of 1 to 2 per cent. of the amount of haloid silver salt present. The prepared plates may be bathed for two or three minutes in a solution of 1 to 2 parts of these compounds in 1,000 parts of water and then dried. A few drops of the dilute solution of any of the alkaline salts may be added to the developing solution. It is claimed that in this manner a much higher degree of sensitiveness is obtained.—C. H. B.

*Improvements in or relating to Mixtures or Solutions for Developing or Fixing the Latent Images on Photographic Plates or Sheets.* W. P. Thompson, Liverpool. From C. Spiro, New York, U.S.A. Eng. Pat. 13,523, August 27, 1889. 6d.

THE developing solution is mixed with some yellow or orange aniline dye, such as Aniline orange, or some other colouring matter which absorbs all the rays of high refrangibility. When the plate has been placed in the coloured developer in the dark room, it may be brought out into daylight and the process of development watched, but of course the plate must not be lifted out of the liquid. When development is complete the plate is quickly transferred to the dish containing the fixing solution, which is then covered over. The fixing solution may be coloured with the same orange dye.—C. H. B.

## XXII.—EXPLOSIVES, MATCHES, Etc.

*Perforated Cake-Powder for Ordnance.* G. Quick. Proc. Inst. Civ. Eng. 1888—89, 107.

THIS paper describes a new modification of powder, by means of which it is proposed to obviate some of the disadvantages of the powders now in use for military purposes. Among such disadvantages are mentioned the large amount of heated and sometimes fused residue left in the gun, the irregularity of the velocity and pressure produced, and the erosive action upon the bore of the gun. Although the brown or cocoa powder gives better results in general, in regard to moderate pressure, than black powder, yet the amount of residue which it leaves is greater. The author claims that his method of forming the "propelling material" is equally applicable either to the new chemical propelling materials, or to the old varieties of powder.

After considering the relation between the pressure and expansion of the gases produced by the combustion of powder in the bore of the gun, the conclusion is arrived at that the best results are to be looked for by using a slow burning powder rather than by increasing the air-spacing of the charge. The rate of burning of a powder is dependent upon various modifications during manufacture, and upon the pressure of the atmosphere of fire to which it is exposed. With most powders the area of combustion surface decreases

as the time increases, while the object to be aimed at is that the pressure shall very rapidly reach its maximum, which shall be maintained constant till the completion of combustion.

By making the surface increase as combustion proceeds the pressure can be made approximately constant during the time combustion is proceeding.

When a cylindrical block of powder, pierced by a hole, is burnt, the surface will decrease as time increases; but if, in addition to the centre hole, a number of smaller ones are ranged round it, then it will be possible to prevent the surface from diminishing as combustion proceeds, and it may even be increased.

The form of powder proposed by the author, and of which illustrations accompany the paper, is that of circular discs with one central circular perforation, also circular in section. Alternate quadrants of the cake are in relief, so that when two cakes are placed together the raised quadrants of the one fit into the sunk ones of the other and the two cakes are, in a manner, locked, so that all the perforations are in line parallel with the axis through the whole length of the cartridge. The quadrants are dished or somewhat hollowed out towards the centre, to permit of the flame readily reaching the whole surface of the cakes. In forming a cartridge a number of these cakes are united by means of a waterproof cement, which is highly combustible and leaves only a very small amount of residuum.

The author believes that the pressure generated in the bore of a gun charged according to his system may be so regulated that it would be possible to discharge shells containing high explosives, such as dynamite.

Although the calculations are made on the assumption that the perforated powder cakes will not break up during the period of combustion, yet it is not expected that this will be found mathematically true in practice. The experiments which are referred to show, however, that the assumption is true enough for all practical purpose.

The author summarises the conclusions which he has arrived at as follows:—1. The pressure should, if possible, be maintained at its maximum till the projectile has travelled some considerable distance up the bore. 2. This can be most satisfactorily obtained by using a powder whose surface of ignition increases as combustion proceeds, or remains practically uniform. 3. That a comparatively low maximum pressure should be adopted if the best results, in the fullest sense of the term, are to be obtained. 4. That the density of the powder should be very high, so as to secure uniformity of combustion, and that the initial ignition and terminal combustion surfaces shall be large enough to secure a sufficiently rapid combustion of this very dense and slow-burning powder, so that none may be blown out of the gun in an unconsumed state. 5. That the air-spacing should be reduced to the lowest possible amount compatible with the due ignition of the charge, and with a sufficient channel space to allow of a fair flow of the powder gas direct to the base of the projectile as soon as the charge is ignited. 6. That the powder charge should be so arranged that the whole of it should be simultaneously ignited, in order that each and every element (cake) should be surrounded by an atmosphere of fire equal in pressure in all directions.

The results of exhaustive experiments are given in tabular form, which confirm the advantages claimed for the "Quick" powder over ordinary service powder.—C. N. H.

## PATENTS.

*Improvements in the Manufacture or Treatment of Explosives to better Control Combustion, or Prevent Detonation.* W. R. Hodgkinson, Blackheath. Eng. Pat. 17,456, November 30, 1888. 6d.

In order to render gun-cotton, nitro-glycerin, and other similar bodies less rapidly combustible, and to lessen the tendency to detonate, the inventor mixes certain compounds of aniline, toluidine, xyldine, cumidine, or of other similar amido compounds with the explosive in such proportions as have been found by experience will reduce the rate of

explosion or combustion to the extent required. The compounds of these bases preferably used are their salts with formic, acetic, and oxalic acids, and their derivatives known as formyl, acetyl, and oxetyl compounds. These compounds may be dissolved in nitro-glycerin, but to impregnate gun-cotton with these substances they must first be dissolved in some solvent, such as alcohol, and the dry gun-cotton caused to absorb the solution; the solvent is afterwards allowed to evaporate spontaneously.—W. M.

*An Improved Manufacture of Nitro-Glycerin and Dynamite.* H. Ritter von Dahmen, Vienna, Austria. Eng. Pat. 17,631, December 3, 1888. 4d.

This invention consists in first adding to pure glycerin 5 to 10 per cent. of a mono or higher nitrate of a hydrocarbon of the benzene or toluene group, and then treating this mixture with the usual acids, nitrogen or air being continuously blown through during the reaction. It is asserted that nitro-glycerin produced in this way will not freeze at  $-25^{\circ}\text{C}$ , and is also less liable to explosion by concussion than ordinary nitro-glycerin.—W. M.

*Improved Apparatus and Process for the Manufacture of Nitro-Glycerin.* H. H. Leigh, London. From La Compagnie Forcite, Paris, France. Eng. Pat. 13,907, September 3, 1889. 8d.

This apparatus consists of a horizontal wooden tank, the cover of which is provided with a sight hole and a chimney for the escape of fumes.

In this tank is placed a smaller leaden tank provided with an inclined gutter-shaped bottom, and which can be closed by the cover of the outer tank. Serpentine leaden pipes are placed at different levels within the leaden tank, and are separately supplied with water, so that all or any particular layer of the liquid can be cooled. Perforated pipes are provided for the admission of compressed air for the purpose of rousing and cooling the contents of the tank.

The main feature of this invention consists in a small pot with perforated sides which stands on the bottom of the inner tank, and into which two pipes deliver, the one glycerin in the form of spray, the other mixed acids. The process of manufacture is conducted by first filling the leaden tank about three-quarters full with the mixed acids. The glycerin is then introduced along with further acid, and the nitric acid is thus effected in the pot, and in the presence of strong acid. The nitro-glycerin and excess of acid then disperse into the surrounding tank.—W. M.

*Improved Machinery for the Manufacture of Explosive Cartridges.* H. H. Leigh, London. From La Compagnie Forcite, Paris, France. Eng. Pat. 13,908, September 3, 1889. 8d.

This invention consists in a novel combination of screws whereby the cartridge material is driven through the machine and delivered in a condition of uniform consistency. The main feature is a screw acting under the feeding piston, and two archimedean screws adapted to deliver two rods of cartridges simultaneously.—W. M.

## XXIII.—ANALYTICAL CHEMISTRY.

*Apparatus for Evaporating Liquids in Small Vessels.* W. Hempel. Ber. 22, 2479—2481.

The apparatus is shown in the figure. A is a large inverted Argand lamp fed through the tube B, which may be clamped to the support at any height. The lamp is of porcelain or soapstone. It is fixed to the metal arm by a paste composed

of manganese dioxide and silicate of soda. A porcelain tube passes through the centre of the Argand lamp, on the top of which a groove, E, is formed. The tube is supported by the arm G. F is a glass chimney which rests in the groove E. M is a platform, which is adjustable to any height. L is an inverted beaker with the bottom removed, which

regulates the supply of air by being raised or lowered on the stand M.

To evaporate a liquid in the crucible T, the porcelain tube D, and glass tube F, are so placed, that the lower end of the former rests in the centre of the Argand lamp. The gas is then lighted, and the gas regulated to give a small flame. The crucible is placed on the support M, with a sheet of asbestos between the two, and upon this the open beaker. The support is then raised so as to rest about 7 mm. below the flame of the Argand. The porcelain cylinder is now lowered almost to the surface of the liquid in the crucible. The decomposition of clays and fluorides may be performed with the greatest readiness, as no portion of the apparatus which comes in contact with acid fumes is attacked.—J. B. C.

*Lecture Experiment in Agricultural Chemistry.* M. Müller.  
Zeits. f. angew. Chem. 1889, 501—502.

THE sketch shows an arrangement of apparatus for demonstrating the absorbing power of earth for soluble salts in dilute solution.

The method is one of upward filtration, which allows of control over the rate of flow of the solution, and ensures that the earthy material is thoroughly permeated. The glass tube A is about 75 cm. long and 4 to 5 cm. in diameter, closed at each end with a perforated rubber cork. A small layer of glass wool at either end serves to keep the earth in its place. The solution is placed in B, and its flow is regulated by a screw clamp at c. A glass T-piece at e serves to deliver a sample of the unfiltered solution, whilst the filtered liquid runs out at b. The best kind of material for the experiment is a sandy earth, poor in humus substances, and unmanured. It should be allowed to dry in the air, and sifted from coarse particles. The solutions used must be dilute: for example, a litre may contain 1.5 grm. of potassium carbonate or crystallised sodium phosphate, or 0.1 grm. of ammonium sulphate. Litmus, ammonium molybdate solution, or Nessler's test may be

used in each case respectively to render the change in the solution visible to an audience. The solution should pass slowly through the soil. A striking experiment may be

made by filling the tube with turf and passing through it some foul refuse water, when a disappearance of the smell will show the distinctive absorptive powers of the soil.

—G. H. B.

*Technical Gas Analysis.* W. Thörner. Zeits. f. angew. Chem. 1889, 641—650.

THE author recommends the use of only such burettes as are surrounded with a cooling jacket, such jacket being connected with a reservoir containing water of the temperature of the room; it is much more satisfactory to have the jacket fused on to the burette and not attached merely by corks or rubber stoppers, which in time are very apt to leak.

In the examination of *generator gas*, *water gas*, *coal gas*, &c., after removal of carbon dioxide and hydrogen in the usual manner, the heavy hydrocarbons of the ethylene and benzene series are absorbed by means of fuming sulphuric acid. The pipette necessary may be fitted with ground glass capsules, and the upper bulb should contain pieces of glass. Absorption of carbon monoxide is easily carried out by means of a fresh hydrochloric acid solution of cuprous chloride. Hydrogen can then be removed by means of palladium asbestos. If the gas still contain methane, as is the case in generator gas, and especially coal gas, the dilution caused by addition of atmospheric air becomes inconvenient; the accompanying Figure (1) shows a very handy way of introducing gases necessary for combustion. The apparatus is of exactly the same size as the usual absorption apparatus and may be easily connected with the measuring burette; one limb of the U-tube is divided into 0.5 cc. and contains two platinum electrodes, the other limb contains one, so that at will oxygen, hydrogen, or electrolytic gas may be obtained and measured and then drawn into the gas burette. Fig. 2 shows a very convenient form of apparatus for burning methane with oxygen; the wires *a a* are of silver, and are thick, so that fracture of the bulb by heating is avoided; these wires are connected inside the bulb by a thin platinum wire, which, when heated by the electric current, brings about the combustion of the

methane. Combustion with electrolytic gas may be carried out in a similar apparatus, an elongated thick walled cylinder taking the place of the combustion bulb, the usual pair of

Fig. 1.

Fig. 2.

platinum wires taking the place of the silver and platinum wires, and a rubber stopper closing the further bulb.

For the *valuation of soda*, or determination of carbon dioxide in minerals, where this may be liberated in the cold by acids, the following apparatus (Fig. 3) serves well.

Fig. 3.

The flask K has a capacity of 100 cc.; into it is weighed a quantity of the dry substance, about 0.25—0.5 gm. The small 50 cc. funnel C contains hydrochloric or sulphuric acid, saturated with carbon dioxide by addition of a small quantity of sodium bicarbonate. During the experiment the flask is kept cool as shown. A is connected with the gas burette and before the experiment levelling is performed by aid of the clip B. Now, by allowing the acid to flow from C into K, the carbon dioxide is evolved, and its quantity ascertained by the volume of gas collected in the burette.

To determine the quantity of *carbon dioxide dissolved or in combination in beer, wine, &c.*, the sample is boiled with hydrochloric or sulphuric acid in a long-necked flask, the neck of the flask being surrounded by a condenser; the gases evolved are received in a collecting vessel, being

Fig. 4.

finally completely displaced from the boiling-flask by running in water; from the collecting vessel they are transferred to a burette and the  $\text{CO}_2$  is determined in the usual way.

To determine volumetrically the amount of carbon in iron and steel the apparatus shown in Fig. 4 may be conveniently used. 0.5 gram of pig iron, spiegeleisen, &c., or 2.5 grms. of steel are introduced into a flask of 150 cc. capacity, along with 10 cc. of a saturated solution of copper sulphate which has been previously filtered through asbestos; the whole is shaken several times, and, after about five minutes, are added for every gramme of iron 5 cc. of a 100 per cent. chromic acid solution. The ground-glass stopper *a*, carrying the condenser *C* and tap-funnel *B*, is inserted, and from *B* about 120–130 cc. of sulphuric acid (sp. gr. 1.594) is slowly run in until the flask is nearly full. The condenser is then immediately connected, by means of the tube *r* and three-way cock *h*, with the burette *D*, which is surrounded, as shown, with condenser. The contents of the flask are next brought gradually to the boil, and are kept boiling for about half an hour. At the end of this time after withdrawal of the flame the whole of the gas may be driven from *A* by running in water from *B*, and finally so much air is admitted that the volume reaches nearly 100 cc. The  $\text{CO}_2$  is then determined by absorption in *K*. From the quantity of  $\text{CO}_2$  of course the amount of carbon may be calculated, correction being made for temperature and pressure. Comprehensive tables giving the carbon corresponding to different quantities of  $\text{CO}_2$  at various temperatures and pressures are given in the original article. As the gas volumes are often small and require to be very accurately measured, the vessel *D* has been narrowed below, the narrow portion showing readings from 75 to 100 cc. This method of determining *C* in iron gives results very closely agreeing with those obtained gravimetrically. The tables above named are of course of the greatest use in all cases where  $\text{CO}_2$  is volumetrically determined.—T. L. B.

*Continuous Recording Apparatus for the Detection of Sulphuretted Hydrogen in Coal Gas.* Ledig. *J. T. Gasbeleucht.* **32**, 925–928.

THE apparatus consists of a strip of paper, dipped in lead solution, driven by the counting mechanism of a small gas-meter, so that a new portion is continually exposed to the action of the gas to be tested, which is kept streaming through the vessel containing the paper strip, at the rate of 50 litres an hour. The strip enters and leaves the atmosphere of gas by mercury traps, and only exposes a length of 2 cm. at any given instant, and travels that distance in one hour. Thus a continuous record of the purity of the gas in respect of sulphuretted hydrogen is obtained.—B. B.

*A New Application of Potassium Ferrieyanide.* G. Kassner. *Chem. Zeit.* **13**, 1302, 1338.

POTASSIUM ferrieyanide in alkaline solution is well known as a useful oxidising agent. It will doubtless also in course of time be used for bleaching of yarn and textile fabric when the price is more moderate.

When peroxide of hydrogen is mixed with an alkaline solution of ferrieyanide a lively, often violent, evolution of oxygen takes place, which may be represented by the following equation in two phases:—

I.

II.

This reaction can be turned to good account as a means of obtaining quickly a regular stream of pure oxygen gas. An undoubtedly pure gas is obtained, which is not the case with potassium chlorate.

The author also considers it preferable to the method of Gohring (*Chem. Zeit.* **13**, 660; also this Journal, 1889, 84), by using hydrogen peroxide and manganese dioxide, or

that of Lindner (this Journal, 1885, 508), by means of sulphuric acid, potassium permanganate, and hydrogen peroxide.

The author recommends 58 grms. of potassium ferrieyanide with 100 cc. of 3 per cent. hydrogen peroxide, which would yield two litres of pure oxygen.—D. A. S.

*Double Sulphocyanides of Iron.* G. Krüss and H. Morah. *Ber.* **22**, 2061–2064.

THE authors have prepared the following double sulphocyanides:—

$\text{Fe}(\text{CNS})_3 \cdot 9 \text{ KCNS} + 1 \text{ H}_2\text{O}$ .—The salt is obtained by adding the calculated quantity of potassium sulphocyanide to a neutral solution of ferric sulphocyanide. The salt is insoluble in dry ether. In moist ether it is decomposed into its constituents, potassium sulphocyanide, which is insoluble, and the ferric salt which dissolves with a red colour.

$\text{Fe}(\text{CNS})_3 \cdot 3 \text{ KCNS}$ .—The salt is prepared in the same manner as the above, using 3 molecules of the potassium salt to one of the ferric salt. It is very hygroscopic. The colour is more orange than the above double salt, and has no green metallic appearance. The dark red colouration, which ferric salts give with potassium sulphocyanide, is due to the salt containing 9 molecules of  $\text{KCNS}$ , which must therefore be added in excess.—J. B. C.

*Qualitative Analysis of the "Iron Group."* F. Mayer. *Ber.* **22**, 2627–2630.

THE author uses sodium acetate for the separation of zinc and manganese from aluminium and iron, the latter being precipitated completely on boiling as basic acetates. If chromium is present it is necessary to have about 5 atoms of iron as ferric salt to 1 of chromium to ensure complete precipitation of this metal, otherwise some chromium is liable to remain in solution. The separation is performed as follows:—The ammonium sulphide precipitate containing chromium is dissolved in dilute hydrochloric acid, oxidised with nitric acid. This solution is tested for iron, and then ferric chloride and sodium acetate added and a sample boiled and filtered. The filtrate, on adding hydrogen peroxide and caustic potash, should give no yellow colouration, otherwise more ferric chloride must be added to the original solution. This solution should not be boiled until an excess of iron is present. The precipitate and filtrate are then treated in the usual way.—J. B. C.

*On the Electrolytic Estimation of Antimony.* A. Leerenier. *Chem. Zeit.* **13**, 1219.

IN Classen's process for above, hydrogen gas at rate of .5 to 2 cc. per minute is passed. The author finds that 5 cc. per minute may be passed without impairing the accuracy of the estimation, and of course saving much time. (Compare this Journal, 1889, 258.)—D. A. S.

*Electrolytic Separation of Cadmium from Copper.* Smith and Frankel. *J. Franklin Inst.* August 1889.

CYANIDE solutions (see this Journal, 1889, 639) were found very suitable for separating cadmium from copper. The conditions most favourable are essentially the same as those just recorded. The separation is most complete, copper not being found in any of the deposited cadmium, and the filtrate being quite free from cadmium (see page 80).

—W. W. H. G.

*Copper Sulphate as an Indicator in Titration of Zinc and Manganese.* F. Moldenhauer. *Chem. Zeit.* **13**, 1220.

STRIPS of an almost smooth filter paper are drawn through a 4 per cent. solution of copper sulphate and dried quickly.

Decinormal potassium ferrieyanide solution is added to an ammoniacal solution of the zinc to be estimated, until the end reaction is shown by a drop of the solution colouring the prepared paper slightly red. This occurs when 0.1 to

0.2 cc. of ferrocyanide is in excess in 100 cc. of ammoniacal solution. The author prefers to titrate with a warm solution of zinc.

Manganese ore is dissolved in sulphuric acid, filtered to separate lead (which must not be present), the filtrate precipitated with ammonia, filtered, washed, redissolved in sulphuric acid, reprecipitated, and refiltered. The filtrates are made up to a known volume and run from a burette into a measured amount of decinormal ferrocyanide until the red colour is no longer shown by placing a drop of solution on the copper sulphate paper. The author notices the fact that while potassium manganese ferrocyanide (*sic*) contains only one hydrogen equivalent, the precipitated zinc ferrocyanide corresponds to two equivalents.—D. A. S.

*A New Application of Peroxide of Hydrogen in Analysis.*  
C. Hiepe. Chem. Zeit. **13**, 1303.

In analysis of alloys the author recommends adding caustic soda to the solution of the fused mass of sulphides, heating to boiling, and adding hydrogen peroxide till the yellow colour is gone. The polysulphides are oxidised directly to sodium sulphate. No more peroxide than just suffices should be added.

The peroxide must of course be pure, and should be tested. The author mentions he has found in the residue of commercial hydrogen peroxide an inexplicable impurity, namely, magnesium chloride.—D. A. S.

*Müller's Method for Estimating Oxygen in Water.*  
R. Hofelman and K. Barth. Chem. Zeit. **13**, 1337.

MAX MÜLLER described (this Journal, 1889, 993) an ingenious and rapid iodometric method of estimating free oxygen in water. The authors contend that in presence of organic matter false results are obtained.—D. A. S.

*Estimation of Cadmium in Cadmium Dust from Zinc Manufacture.* W. Minor. Chem. Zeit. **13**, 1376—1377.

THE estimation of cadmium in the by-product cadmium dust presents some difficulties. The author suggests the following process:—

Twenty grms. of the cadmium dust are dissolved in hydrochloric acid (avoiding excess of acid), filtered, filtrate diluted to 1 litre; 50 cc. (= 1 gm. Cd dust) are precipitated in the usual way with sulphuretted hydrogen, in a beaker of 500 cc. capacity. The precipitate is filtered, dried at 110°, and weighed. The precipitate is redissolved in hydrochloric acid (having calculated from the weight of the precipitate the exact amount required for solution) and reprecipitated with sulphuretted hydrogen. This treatment is repeated twice. In order to obtain cadmium sulphide of constant weight, it is necessary thus to precipitate it four times. Excess of acid decomposes the sulphide. Washing the sulphide precipitate with alcohol and carbon disulphide is quite superfluous.—D. A. S.

*Technical Analysis of Wolframite.* B. Setlik. Chem. Zeit. **13**, 1474.

THE author recommends that the mineral be first finely ground, and then dried at 110° C. Three to five grms. are taken for analysis, and fused for two hours in a platinum crucible with 3—4 times the amount of sodium carbonate. The fused mass is extracted with water, and the solution is filtered, and the residue washed until the washings are no longer rendered turbid by hydrochloric acid. The solution is now heated and poured into excess of hydrochloric acid, and boiled for half an hour. The precipitate, which consists chiefly of tungstic oxide, but may also contain stannic oxide, silica, and molybdic acid (the last, however, is rarely found), is washed, dried, and burned, after removal from the filter, and weighed. It is then treated with hydrofluoric acid in order to remove the silica.

If tin be present the precipitate, after removal of the silica, is fused for half an hour with cyanide of potassium, extracted with water and filtered from the metallic tin.

The tin is dissolved in ferric sulphate and its amount found from titration with permanganate. To estimate the iron and manganese the residue insoluble in water is dissolved in hydrochloric acid, and the solution is divided into two equal portions, one of which is reduced with zinc and titrated with permanganate, and the other precipitated with sodium carbonate and oxidised with bleaching powder. The precipitate, after being filtered and washed, is dissolved in a solution of ferrous sulphate of known strength, and the excess of ferrous sulphate titrated back. Wolframite generally contains from 60—80 per cent. of tungstic oxide and from 10—20 per cent. of manganese. This process may also be used for estimating the tungstic oxide in schellite.—W. M.

*Ferric Hydrate as an Indicator in the Determination of Zinc.* W. Minor. Chem. Zeit. **13**, 1566.

IF the ferric hydrate is freshly precipitated an excess of two drops of sodium sulphide solution can be clearly recognised, but if kept for some days, however carefully, it becomes granular and colours slowly with the reagent, so that the end reaction is undecided, and 0.5 to 1 cc. excess of sulphide is required to finish. Ferric hydrate prepared from the commercial chloride or nitrate behaves in the same way. The author recommends the preparation of ferric chloride from ferrous ammonium sulphate, and states that ferric hydrate obtained by precipitating the chloride so prepared with ammonia is a more reliable indicator than lead paper or even sodium nitroprusside.—S. B. A. A.

*Determination of Phosphorus in Pig Iron, Steel, &c.*  
G. Weissmann. Chem. Zeit. **13**, 1604—1605.

THE author has compared various quick methods, and recommends the following modification of Reis's process as the most rapid and accurate:—5 grms. of metal are heated with 30—40 cc. of dilute  $\text{HNO}_3$  (1:5) in an Erlenmeyer flask till the violent evolution of gas diminishes; 30—40 cc. of concentrated  $\text{HNO}_3$  (sp. gr. = 1.41) are then added, and when solution is complete, additions of 5 cc. of a solution of potassium permanganate (containing 15 grms. per litre) are repeatedly made till a brown precipitate of manganese peroxide makes its appearance. The solution is cooled, reduced with hydrogen peroxide, made up to 250 cc., filtered, and 100 cc. taken out. According to the richness of the sample 50—100 cc. of a standard solution of ammonium molybdate prepared as below (*a*) are added, the solution heated on a water-bath to 80—90° C. for one hour, cooled and filtered.

The yellow precipitate is washed three or four times with a dilute solution of ammonium molybdate (1:1), dissolved off the filter paper with dilute ammonia (1:6); the solution should occupy about 50—60 cc. 10—15 cc. of magnesia mixture (*b*) are added drop by drop with constant stirring, taking care not to touch the sides of the beaker. The precipitate is allowed to subside for two hours, filtered, washed five or six times with dilute ammonia (1:6), dried and ignited. The weight in grammes  $\times 13.975$  = percentage of phosphorus. The process can be completed in 4—5 hours, and gives very accurate results. An approximate result is more speedily obtained by Meineke's method (this Journal, 1887, 387) of washing the yellow precipitate first with a 10 per cent. solution of ammonium nitrate, and then with water, drying, igniting at a low heat, and weighing as  $\text{Mo}_2\text{O}_3 \cdot \text{P}_2\text{O}_5$ , of which 1 gm. = 1 per cent. of phosphorus.

(*a*.) 630 grms. of ammonium molybdate are finely powdered and gradually dissolved in 750 cc. of ammonia (sp. gr. = 0.91), and 1,200 cc. of water, filtered and stirred into a mixture of 2,500 cc. of nitric acid (1.41), and 4 litres of water. After standing for two or three days the clear solution is drawn off; 10 cc. = .001 gm. of phosphorus.

Otherwise 500 grms. molybdic acid are dissolved in 1 litre of ammonia (0.91) and 1,100 cc. of water; the solution being added to a mixture of 2,500 cc. of nitric acid (1.41), and 4 litres of water as before.

(*b*.) 160 grms. of magnesium chloride ( $\text{MgCl}_2 + 6\text{OH}_2$ ), and 200 grms. of ammonium chloride are dissolved in  $2\frac{1}{2}$  litres

of water; 500 cc. of ammonia (0.91) are added, the mixture stirred, allowed to stand for a few hours, and filtered; 10 cc. = .04 grm. of phosphorus.—S. B. A. A.

*A New Method of Pyrites Analysis.* P. Jannasch. Jour. prakt. Chem. [2], 40, 233—235.

THE sulphur in pyrites can be accurately estimated in a comparatively short time by the following method, which is more especially advantageous when the sample contains substances which render the application of solvents more difficult but allow of the expulsion of the sulphur in the dry way.

The finely divided pyrites is placed in a small boat and introduced into a combustion tube which can be heated in a small furnace. A current of air (about 150—200 bubbles per minute), dried by means of sulphuric acid and saturated with nitric acid vapour by passing through a Drechsel's flask containing about 50 cc. of fuming nitric acid, is passed through the combustion tube into a tubulated receiver containing 100 cc. of bromine water, to which is attached a Peligot's tube containing 40 cc. of bromine water, and finally through a cylinder of distilled water.

The pyrites is gradually heated, commencing at the hinder portions of the tube, the front parts being also warm to prevent the condensation of the sulphuric acid. In about three-quarters of an hour, the process being at an end, the Drechsel's flask containing nitric acid is removed and the boat is allowed to cool slowly in a stream of air. The sublimation of the sulphur by too rapid heating is to be avoided.

The contents of the receivers are washed into a beaker, the excess of bromine evaporated, the solution mixed with 1 cc. of concentrated hydrochloric acid, heated to boiling and the sulphuric acid precipitated with barium chloride; the precipitate must be carefully washed with boiling dilute hydrochloric acid, to free it from barium nitrate, but any admixture with this salt can be avoided by evaporating completely in a porcelain basin before adding the barium chloride.

The boat containing the ferric oxide, which is quite free from unchanged pyrites, is warmed with concentrated hydrochloric acid, the solution evaporated almost to dryness and the insoluble residue estimated in the usual manner; the iron solution is completely free from sulphuric acid.

Two analyses by this method gave the following results:—

	Per Cent.	Per Cent.
Sulphur .....	52.59.	52.67
Iron .....	45.67	45.52
SiO <sub>2</sub> , &c. ....	1.08	1.12
	<u>99.34</u>	<u>99.31</u>

—F. S. K.

*Estimation of Sulphuric Acid in Presence of Iron.* P. Jannasch. J. prakt. Chem. [2], 40, 236.

THE author and Richards have stated (J. prakt. Chem. [2], 39, 321; this Journal, 1889, 819), that Lunge's method of pyrites analysis is not accurate; but this statement was made with reference to the older method only, the new method having been overlooked. Lunge himself has shown (Handbuch der Soda-Industrie) that his method gives accurate results if the iron is precipitated with a slight excess of ammonia at a moderate temperature before determining the sulphuric acid. The author now confirms Lunge's statement, and gives analyses of a sample of pyrites carried out (I.) by Lunge's improved method, (II.) by the nitric method described in the preceding abstract:—

I.		II. (Average of two analyses.)	
	Per Cent.		Per Cent.
Sulphur .....	52.56		52.63
Iron .....	45.88		45.59
SiO <sub>2</sub> , &c. ....	1.08		1.10
	<u>99.47</u>		<u>99.32</u>

—F. S. K.

*The Determination of Chlorine in Water.* A. Hazen. Amer. Chem. Jour. 11, 409—414.

IN estimating chlorine in water or sewage by titration with silver nitrate solution the results commonly obtained are too high, owing to the fact that the red colour of silver chromate does not become perceptible until a certain excess of silver has been added. Under certain conditions, however, the required excess is constant, and by making the proper corrections very accurate results can be obtained.

The author has made a large number of experiments with a solution of silver nitrate, 1 cc. of which is equal to 0.5 mgrm. of chlorine, prepared by dissolving the calculated quantity of pure silver nitrate in distilled water. The following is an account of his experiences:—

The amount of potassium chromate used has a considerable influence on the results, especially in a large volume. In general, the greater the quantity of chromate used the smaller will be the required excess of silver, but when the quantity has reached a certain point the advantage gained by any further increase is more than overcome by the increase in colour which obscures the exact end-point. 0.001 grm. of potassium chromate per cubic centimetre of liquid titrated was found to be a suitable quantity, but in practice the author employs 0.06 grm.

The required excess of silver solution increases regularly with the volume of the liquid titrated; when 0.06 grm. of potassium chromate is used and the volume is not more than 60 cc., this excess may be represented by the formula  $x = .003v + 0.02$  where  $v$  is the volume of the liquid at the end of titration. Thus with a volume of 3 cc. the correction is 0.03 cc., whilst with a volume of 50 cc. the correction is 0.17 cc.

The required excess of silver solution, in addition to the correction for volume, increases regularly with the amount of the precipitated silver chloride, and is nearly proportional to the amount of the silver solution used. The correction is nearly 1 per cent. of the volume of the silver solution, and may be most conveniently applied by employing a solution containing 1 per cent. more than the theoretical quantity of silver. If the silver solution is standardised against sodium chloride it will be of this strength, and no correction will be required for the amount of the precipitate. If the amount of chlorine is very low the results are somewhat irregular, so that if less than 1 cc. of silver solution is required for 50 cc. of water it is preferable to run in 1 cc. of salt solution and deduct the equivalent of silver solution from the result.

Instead of preparing the silver solution by dissolving the theoretical quantity of silver nitrate it is practically more convenient and better to depend on titrations of salt solutions for its strength, always making the correction for volume.

It is possible by direct titration in this way to get results within 0.05 part of chlorine in 100,000 in clear waters when the chlorine is not higher than 10 parts. When the chlorine is low and greater accuracy is required the water must be concentrated before titration. In such cases excess of sodium carbonate must be added before evaporating, otherwise there may be a serious loss of hydrochloric acid; commonly 0.02 grm. of sodium carbonate, or less is sufficient, and this quantity does not interfere with titration. If too much has been used calcium nitrate may be added before titration, as an excess of nitrate does not influence the result. The water can be concentrated (1) by boiling down 500 cc. or more to 50 cc. with sodium carbonate in a flask; if much organic matter is present the solution becomes brown and must be decolourised with aluminium hydrate, and filtered before titrating. (2) By evaporating on the water-bath with sodium carbonate. (3) By evaporating to dryness and igniting in a radiator: the chlorides are extracted from the residue with hot water and titrated as usual. The last method seems to be most accurate when much organic matter is present.—F. S. K.

*Precipitation of Aluminium and Iron by Means of Ammonia.* G. Lunge. *Zeits. f. angew. Chem.* 1889, 634—635.

THE usual method is to precipitate with slight excess of ammonia, and then to expel excess of ammonia by boiling. Fresenius remarks that this operation should be conducted in a platinum or good porcelain dish, and not in a glass vessel, owing to the glass being attacked. The whole is boiled because the precipitate is, to a slight extent, soluble in free ammonia; if, however, the boiling be continued too long, some of the ammonium chloride which may be present is decomposed, and the hydrochloric acid thereby formed dissolves a portion of the alumina and oxide of iron. A further precaution usually taken is to ignite the precipitate with the blow-pipe before weighing—this because the precipitate persistently retains sulphuric acid (should this be present) in the form of basic sulphates. The author has pointed out, in connexion with the analysis of pyrites (this *Journal*, 1889, 966), that by using only very slight excess of ammonia, and then warming gently for 10 minutes before filtering, a precipitate is obtained which settles well, filters easily, and is perfectly free from sulphuric acid. Still, however, the excess of ammonia dissolves some of the alumina and oxide of iron. It has been pointed out by Fresenius (*Quant. Anal.* II., 807, 6th German edition), and it is a fact too often overlooked, that in presence of ammonium chloride not a trace of alumina goes into solution. This is perfectly in agreement with the author's observations. By adding ammonium chloride and excess of ammonia, and then warming gently, three advantages are thus gained:—(a) there is no danger of decomposing ammonium chloride, since there is no boiling, and hence no danger of thereby getting a portion of the precipitate into solution; (b) the precipitation, filtration, and washing occupy a much shorter time; and (c) igniting with the blow-pipe is rendered unnecessary, as the precipitate contains no sulphuric acid.—T. L. B.

*Determination of Iron and Aluminium in Phosphates.* E. Glaser. *Zeits. f. angew. Chem.* 1889, 636—638.

THE method of determining iron and aluminium in phosphates by precipitating with ammonia and adding acetic acid is not applicable in every case; as, for instance, when calcium and magnesium phosphates are present in addition; again, the results obtained vary with the amount of acetic acid used, aluminium phosphate being soluble in acetic acid. The author proposes the following method, which has been tested with various phosphate mixtures of known composition, and shown to give reliable results. The calcium is separated from the phosphoric acid by sulphuric acid in presence of alcohol, and the iron and aluminium phosphates may then be obtained free from calcium and magnesium without the use of acetic acid:—

Five grms. of phosphate are dissolved in 25 cc. of nitric acid (sp. gr. 1.2) and in 12.5 cc. of hydrochloric acid (sp. gr. 1.12), and the solution is made up to half a litre. 100 cc. of filtrate (= 1 gm. of substance) are transferred to a 250 cc. flask, and 25 cc. of sulphuric acid (sp. gr. 1.84) are added. After the lapse of about five minutes, during which time the flask with its contents has been occasionally shaken, 100 cc. of 95 per cent. alcohol are added, the whole is cooled, and the flask filled to the containing mark with alcohol, and well shaken. Contraction takes place and the flask is again filled to the containing mark with alcohol, and again shaken. The whole is allowed to stand half an hour and is then filtered. 100 cc. of the filtrate (= 0.4 gm. of substance) are transferred to a platinum dish and the alcohol is evaporated away, after which the solution free from alcohol is transferred with 50 cc. of water to a beaker and boiled; ammonia is then added, the whole again well boiled, allowed to cool, and filtered. The residue is ignited and weighed as phosphates of iron and aluminium. A determination may be conveniently carried out in  $1\frac{1}{2}$  to 2 hours.—T. L. B.

*The Götz Method of Determining Phosphorus.* C. Bornmann. *Zeits. f. angew. Chem.* 1889, 638—639.

IT has been stated that this method gives good results only with samples of steel poor in carbon. According to the author, however, the percentage of carbon does not influence the result, if the method be carried out as follows: In a new beaker of about 100 cc. capacity 1.2 grms. of steel is dissolved in 25 cc. of nitric acid (900 cc. of nitric acid of sp. gr. 1.4 to 100 cc. of water); the solution is then concentrated, and 8 to 16 drops of potassium permanganate are added (cast iron requires 8 drops, rail steel 16); the peroxide of manganese is dissolved by addition of 5 to 10 drops of hydrochloric acid (sp. gr. 1.19). Excess of hydrochloric acid is then driven off and the solution concentrated as far as possible. To the hot solution are next added 10 cc. of a 25 per cent. solution of ammonium nitrate, and 25 cc. of Finkener's ammonium nitromolybdate solution. The contents of the beaker are then washed with the aid of a 25 per cent. solution of ammonium nitrate into a small pear-shaped vessel with graduated stem, such vessel having a capacity of about 60—70 cc., and the graduated stem (40 mm. in length and divided into 40 parts) having a capacity of 0.2 cc. The whole is well shaken for about a minute, and the vessel is thereupon filled with 25 per cent. ammonium nitrate solution and fixed into a centrifugal machine prepared for it, and rotated for two minutes at the rate of 1,200 revolutions per minute, after which the machine is stopped as suddenly as possible. The reading on the stem divided by two now gives the amount of phosphorus in hundredths per cent. The results are affected by silicon, if this reaches over 0.25 per cent., in which case silica separates.

The potassium permanganate solution used for oxidation contains 12 grms. per litre. Finkener's molybdate solution is prepared by dissolving 160 grms. of ammonium molybdate in 795 cc. of cold water, adding 320 cc. of ammonia (sp. gr. 0.925), and pouring the whole into a mixture of 1,710 cc. of nitric acid (sp. gr. 1.2) and 1,205 cc. of water, keeping well cooled the while.

The author gives a series of analyses performed by this method, and also gravimetrically; the greatest difference obtained was 0.005 per cent. of phosphorus.—T. L. B.

*The Estimation of Phosphorus in Phosphor-Tin.* W. Hempel. *Ber.* 22, 2478.

THE alloy is heated in a current of chlorine and the chloride led into 10 cc. of concentrated nitric acid. The phosphoric acid is precipitated in the solution with molybdic acid in the usual way.—J. B. C.

*Estimation of Ferrocyanogen Compounds in the By-Products of Gas-Manufacture.* R. Gasch. *Journ. f. Gasbeleucht.* 1889, 966—971. (Compare this *Journal*, 1889, 732—733.)

THE author has modified the method proposed by Zulkowski by using a 1 per cent. solution of uranium acetate instead of ferric chloride as indicator, and by employing a more dilute solution of zinc sulphate, 20.62 grms. of the crystalline salt per litre, which is standardised against pure potassium ferrocyanide. The process applied to old gas-purifying material is as follows: 20 grms. of the finely pulverised dry substance are triturated in a warm mortar with warm (not above 50°) 15 to 20 per cent. caustic soda, washed into a 200 cc. flask, made up to mark (the quantity of soda and water used being noted), and filtered direct into a burette. The solution is run into 10 cc. of the zinc solution which has been strongly acidified with sulphuric acid and heated to 70°—86° C. until a drop in excess is indicated by the browning of the drop of uranium acetate on the porcelain slab. The method may be applied to determine cyanogen compounds by previously converting them into ferrocyanides by boiling with caustic soda and ferrous sulphate.—D. A. L.

*A Reaction for Cocaine.* O. Lerch and C. Schürges.  
Schweiz. Wochenschr. Pharm. **27**, 293.

THE cocaine to be tested is dissolved in water and a drop of ferric chloride solution is added. On boiling the solution an intense red colour is developed owing to the formation of benzoic acid. Benzoyl-ecgonine also gives this reaction, but this substance differs considerably from cocaine in melting point and solubility. Cocaine is readily soluble in ether, benzoyl-ecgonine is not soluble.—H. T. P.

*Microscopic Examination of Paper.* W. Herzberg. Mitt. Königl. tech. Versuchs. **1889**, **3**, 113—115.

THE method adopted for preparing the paper fibre for microscopical examination consists in treating the sample with 500 cc. of water to which has been added 5 cc. of a concentrated solution of caustic soda, boiling and shaking until the paper is disintegrated, draining and washing from the alkaline liquor on a fine sieve, and thoroughly separating any clots of fibre by shaking in a 100 cc. flask with distilled water and a large number of small garnets, by which means an emulsion of single fibres with water, well suited for the purpose in hand, is obtained.

The discrimination of fibres of different origins cannot with certainty be effected by any of the colour reactions that have been from time to time proposed.

A reagent composed of 20 cc. of water, 2 cc. of glycerol, 1·15 grms. of iodine, and 2 grms. of potassium iodide is useful, not so much on account of the fairly characteristic colourations it gives with paper fibre from various sources, as because of the increase of clearness and differentiation of structure under the microscope which it effects.—B. B.

*Solidifying Points of Viscous Oils.* Holde. Mitt. Königl. tech. Versuchs. **1889**, **3**, 119—126.

SEEING that both mineral and fatty oils may be regarded as solutions of bodies of higher melting point in others of lower melting point, it is not surprising that it is difficult to assign to such mixtures definite solidifying points; the temperature at which any deposit appears may be regarded as that of the commencement of solidification. Between this point and the completion of the process a certain liberation of heat occurs, which is usually more considerable for mineral than fatty oils; in the latter, however, the change of state is generally sharper. Besides these inevitable difficulties, avoidable causes of error are the failure to expose the oil to the cooling-bath for a sufficient period, and the irregular agitation of the sample, *e.g.*, *Salkowsky* found that a cod-liver oil which remained perfectly clear when cooled for a short time to  $-15^{\circ}\text{C}$ ., became quite solid after several hours' exposure to  $-4^{\circ}\text{C}$ .

The author proceeded, therefore, to investigate these two factors, at present somewhat neglected. The tests were carried out in test-tubes 15 mm. in diameter, filled to a height of 3 cm., and *Hoffmeister's* method of cooling (Mitt. Königl. tech. Versuchs. **1889**, **1**, 24; this Journal, **1889**, 423) was employed. The results are recorded in voluminous tables unfitted for useful abstraction.

The conclusions arrived at were:—

Provided agitation be avoided, vegetable oils require very lengthy exposure to cold before beginning to solidify. For example, rape oil, which remained clear for two hours at  $-3^{\circ}\text{C}$ ., gave a white deposit after three hours, and was in great part of the consistency of tallow after 6½ hours; a mustard-seed oil took 5½ hours' and one day's cooling to reach the same conditions respectively; this peculiar behaviour accounts for the low solidifying point usually quoted, *viz.*,  $-18^{\circ}\text{C}$ ., and may be viewed as analogous to that of a supersaturated solution, a view strengthened by the hastening of solidification caused by the introduction of a particle already solid. Mineral oils deposit solid matter sooner than vegetable oils, and reach their final condition for any given temperature more quickly than the latter. Stirring, instead of increasing their consistency as in the case of vegetable oils, diminishes it, by breaking up the network of paraffin or vaseline-like particles which has

formed. It follows that a mineral oil should be tested by cooling to the desired temperature without agitation, and inclining the tube, or otherwise judging of its consistency only after the lapse of one hour.—B. B.

*The Detection of Sesame Oil.* M. W. Bishop. J. Pharm. Chim. **1889**, **20**, 244.

SESAME oil, when treated with a mixture of equal parts of nitric and sulphuric acids, quickly assumes a fine green colour. With a freshly prepared solution of cane sugar in hydrochloric acid of 22° B. it yields, on shaking, a cherry-red tint. Fresh sesame oil suffers no change when agitated with pure hydrochloric acid of 21—22° B. (2 volumes of oil to 3 volumes of acid). If, however, the oil be previously exposed to air and light for a few days, it gives with hydrochloric acid a green mixture. On standing, the acid layer which separates alone is coloured. In the case of old oil the acid deposits bluish violet flakes. Very old oil, which has been exposed for years to air and light, imparts to the acid an almost blue colour. On standing a copious flocculent blue precipitate separates from the acid, the latter becoming of a clear green colour. Sesame oil, which has been deprived of its colouring matter by hydrochloric acid, still gives a cherry-red tint with a solution of cane sugar in hydrochloric acid. When testing for sesame oil in olive oil it is best to expose the sample to bright light for a few days. Then mix about 6—8 cc. of the oil with 12—14 cc. of hydrochloric acid of 21—22° B., and shake violently in a stoppered cylinder of about 35 cc. capacity.—H. T. P.

*The Detection of Resin Oil in Castor Oil.* H. Gilbert. Chem. Zeit. **13**, 1428.

THE ordinary tests for castor oil prescribed by the German Pharmacopœia do very well for the detection of fatty oils, but fail in the presence of resin oil. A sample of castor oil recently examined by the author answered all the ordinary tests satisfactorily, but its taste and smell were suspicious. On saponification it was found to contain 19 per cent. of resin oil, and its saponification equivalent was 126, whilst the saponification equivalent of pure castor oil is, according to Valenta, 180—181·5. Pure castor oil, when agitated with an equal bulk of nitric acid of 1·31 specific gravity, is turned slightly brown, the acid remaining colourless. Under the same conditions resin oil is turned almost black, and the acid assumes a yellowish-brown tint. The adulterated sample of castor oil yielded, on treatment with nitric acid, the colour reaction of resin oil, but of course in a degree corresponding to the dilution.—H. T. P.

*Comparison of Different Methods of Determining Free Acid in Oils.* Holde. Mitt. Königl. tech. Versuchs. **1889**, **3**, 116—119.

GEISSLER'S method, consisting in dissolving the oil in ether-alcohol and titrating it with decinormal alcoholic (50 per cent.) alkali, is accurate and can be used in all cases, save where the oil is so dark coloured as to hide the change of the indicator (phenolphthalein) used. By employing a cylinder about 4 cm. in diameter instead of a flask, this difficulty is much lessened. The process is especially suited for clear mineral oils. *Burstyn's* plan of shaking the oil with an equal volume of alcohol, drawing off and titrating an aliquot portion, is fallacious, as the whole of the free fat acid is only extracted by repeated treatment with alcohol, and thus the results are low when compared with those given by Geissler's method, *e.g.*, a refined rape oil containing 0·730 per cent. of acid, calculated as  $\text{SO}_3$ , gave only 0·374 per cent. when thus treated.

*Merz* shakes the oil with alcohol in a stoppered flask and titrates the mixture with repeated agitation. This gives accurate results, and is well adapted for oils containing a considerable quantity of free fat acid, as if treated by Geissler's method they require an inconveniently large amount of alcohol to prevent the oil being precipitated from its ethereal solution by the standard caustic alkali in weak alcohol.

Burstyn's physical method, which consists in shaking the oil with alcohol of known specific gravity and deducing the quantity of fat acid it extracts by the increase in density it suffers, is quite untrustworthy; e.g., an oil containing 0.091 per cent. of acid, calculated as  $\text{SO}_3$ , gave 0.280 per cent. Many causes conduce to this result; among them may be mentioned the different specific gravities of the acids extracted, the error caused by the presence of a mineral acid, such as sulphuric acid, and the varying quantity of neutral oil dissolved. The following method is adapted for dark opaque mineral oils: 25 cc. of the oil is shaken with 50 cc. of absolute alcohol in a stoppered cylinder about 2 cm. in diameter, and the mixture allowed to settle; 25 cc. of the alcohol is then drawn off, 10 cc. of ether added if turbid, and titrated with decinormal caustic soda. If more than 2 cc. be used, the rest of the alcohol is poured off, another 50 cc. added, and the process repeated.

The free acid has been calculated as  $\text{SO}_3$  throughout the paper for the sake of uniformity.—B. B.

*The Examination of Oils.* F. Jean. J. Pharm. Chim. 1889, 20, 337.

THE author recommends a method of examining oils which depends on the determination of the specific gravity, the melting point of the fatty acids, the heat evolved on mixing the oil with sulphuric acid, and lastly of the refractive index. The specific gravity is determined by means of Westphal's areothermic balance. The melting point is determined in an apparatus consisting of a thin-walled U-tube, the limbs of which are of unequal length. The shorter limb ends in a small funnel through which the melted substance is introduced, in quantity sufficient to fill the bend of the U-tube. A platinum wire is passed so far into each limb that the two ends nearly meet in the bend. The tube is supported in a beaker of water by means of a clamp which also carries a thermometer. The two platinum wires are connected to an electric bell and battery, and a little mercury is poured into one of the limbs of the U-tube. On warming the water in the beaker, the fat melts and allows the mercury to pass to the lower portion of the bend, where it closes the circuit between the two platinum wires, and as a consequence the bell rings. At this moment the temperature is noted. The heat evolved by mixing the oil with sulphuric acid is determined by means of the following apparatus (see diagram) named by the author "Thermoeleometer."

A is a small vessel, 4 cm. in diameter and 6 cm. high. It is graduated at 15 cc., and serves for the reception of the oil. B is the acid holder, and is fitted with a hollow glass stopper, to which is attached the india-rubber tube R. The neck of the acid-holder carries a clamp, in which a thermometer is fixed. 5 cc. of sulphuric acid of 65° B. are placed in the acid-holder, and 15 cc. of the oil to be tested

in the vessel A. The oil is heated up to about 40°–50° C., when the acid-holder B is placed in it, and the apparatus is allowed to cool, with occasional stirring, to 30° C. To hinder further cooling it is then placed in the felt-lined brass case E. The acid is now forced out of B, through the small tube, by blowing through R, the oil and acid are well mixed, using B as a stirrer, and the maximum temperature is noted. If the oils are much oxidised they must be first treated with alcohol, or, better still, saponified, and the fatty acids separated and employed for the determination of the degree of heating. The author obtained the following numbers with the thermoeleometer:—

Fatty Acids.

Olive oil.....	41.5	45
Linseed oil.....	61	109
Colza oil, Pas de Calais.....	37	44
„ India.....	37	46

For the determination of the refractive index the author and Amagat employ a modification of Tramm's oleo-refractometer. Each oil possesses a characteristic refractive power which varies but slightly, according to the source of the oil. The author gives the following deviations for various oils:—Olive oil,  $1\frac{1}{2}^{\circ}$ – $2^{\circ}$ ; earth-nut oil,  $4^{\circ}$ – $5^{\circ}$ ; colza oil,  $16\frac{1}{2}^{\circ}$ – $17\frac{1}{2}^{\circ}$ ; sesame oil,  $17^{\circ}$ ; cotton-seed oil,  $20^{\circ}$ ; castor oil,  $40^{\circ}$ ; linseed oil,  $53^{\circ}$ ; hemp oil,  $33^{\circ}$ ; poppy oil,  $30^{\circ}$ ; maize oil,  $27^{\circ}$ ; sweet almond oil,  $6^{\circ}$ ; cod-liver oil,  $42^{\circ}$ ; whale oil,  $30\frac{1}{2}^{\circ}$ . All the above deviations are to the right; the following oils give a levo-reading:—Sheep-trotter oil,  $0^{\circ}$ ; horse-hoof oil,  $-12^{\circ}$ ; ox-foot oil,  $-3^{\circ}$ ; sperm oil,  $-12^{\circ}$ . Olive oil from Nizza, giving a deviation of  $1\frac{1}{2}^{\circ}$ , when mixed with 10 per cent. poppy oil, gave  $6\frac{1}{2}^{\circ}$ , and on addition of 20 per cent. poppy oil the reading was  $10^{\circ}$ . Mixed with 10 per cent. cotton-seed oil the deviation was  $3^{\circ}$ , and with 20 per cent.  $5^{\circ}$ . Pure poppy oil, giving a reading of  $34^{\circ}$ , when mixed with 20 per cent. of earth-nut oil, only yielded  $25^{\circ}$ ; 20 per cent. of cotton-seed oil added to castor oil diminishes its reading by  $7^{\circ}$ . The resin and heavy mineral oils are readily detected, in admixture with animal and vegetable oils, by their high refractive power. According to the author, an oil may positively be regarded as pure when its specific gravity, refractive power, and degree of heating with sulphuric acid correspond with the values obtained for a typical sample of known purity.—H. T. P.

*The Technical Examination of Glues.* W. Kalmann, Leipziger Monatsch. für Textil-Ind.

THE author gives the results of his experience in examining glues used for sizing warps.

He finds that Kissling's method (this Journal, 1887, 565–566) for ascertaining whether glue is made from leather or from bones, and based on the different behaviour of the ashes on heating, and on their qualitative analysis, is a reliable one. For the purpose mentioned above, bone glues are almost exclusively used.

Since in woollen manufacturing both dyed and undyed wool is sized, glues used for the purpose should be free from acid. The author found that glue solutions which did not alter litmus, might give an acid reaction with phenolphthalein, probably owing to the presence of an organic acid which does not effect litmus. He estimated the amount of this acid by titrating directly with decinormal alkali and using phenolphthalein as indicator.

Glue to be used in woollen manufacturing, besides being neutral to litmus, and therefore free from mineral acids, should contain no sulphurous acid, whether free or in the form of normal sulphites. It was found that glue containing these substances is capable of producing light patches on dyed wool, which defect is sufficient to exclude any such glue from use in the woollen manufacture. Sulphurous acid may be estimated by titrating the solution to which starch paste has been added with about  $\frac{1}{10}$  normal iodine solution. For this titration the same solution can be used as that in which the acid has been estimated with alkali and phenolphthalein, thereby shortening the examination.

In order to determine whether organic matter contained in glue affected the iodine and thus made the amount of sulphurous acid too high, the author has often estimated after the iodine titration the hydriodic acid which is produced,  $M_2SO_3 + H_2O + I_2 = M_2SO_4 + 2HI$ , with decinormal alkali, and has always found the two estimations to coincide, proving that the iodine is not affected. This additional titration requires very little time, and should be made as a check.

The following is the method:—1 gram. of the coarsely powdered sample of glue is dissolved in water on the water bath, the solution first tested with blue litmus paper and then titrated with decinormal caustic alkali, using phenolphthalein as indicator, until it turns red. The liquid is then

cooled, starch paste added and then iodine solution until it turns blue. The blue solution is next decolourised with a drop of sodium bisulphite solution and again titrated with decinormal caustic alkali, until it becomes red. The amount of decinormal alkali used in the last titration is equivalent to the amount of sulphurous acid contained in the glue, and also to the iodine solution.

In determining the comparative value of samples of glue, the water and ash estimations are of chief importance, but with glues to be used in the woollen manufacture, care should also be taken that they contain no ingredient which affects colouring matters.

The following table contains the results of some of the author's analyses:—

No.	Variety of Glue.	Amount taken.	Reaction with Litmus.	Na <sub>2</sub> O equivalent to Amount of Free Acid present.	Amount of Iodine required.	SO <sub>2</sub> .	Amount of $\frac{1}{10}$ N Alkali Corresponding to the Iodine, cc.	Amount of $\frac{1}{10}$ N Alkali taken, cc.	Ash.
		Grams.		Per Cent.		Per Cent.			Per Cent.
1	Gelat'n.	3.363	Faintly acid.	0.46	0.60336	0.03	..	..	..
2	Bone-glue.	3.0478	" "	1.32	0.055410	0.16	..	..	3.55
3	" "	3.1535	" "	0.81	0.023611	0.20	..	..	3.69
4	" "	3.3524	Acid.	1.56	0.127882	0.16	10.1	10.3	..
5	" "	3.6412	Neutral.	0.14	0.016262	0.11	1.28	1.3	..
6	" "	3.3770	Acid.	2.02	0.185522	1.41	11.16	11.6	1.63
7	" "	3.1330	Neutral.	0.67	0.011827	0.09	..	..	2.21
8	" "	2.9808	Faintly acid.	0.95	0.042427	0.26	..	..	2.37
9	" "	3.1263	Acid.	1.49	0.110418	1.03	11.06	11.2	1.92

Samples 2, 4, 6 and 9 on material dyed with logwood produced distinctly lighter spots.

According to the foregoing the requirements for glue to be used in the woollen manufacture are as follows:—

1. The solution of the glue should be neutral to litmus paper, or at the most only slightly acid.

2. The amount of free acid which reacts with phenolphthalein should not correspond to more than 1 per cent. of Na<sub>2</sub>O.

3. The amount of sulphurous acid contained should not exceed 0.5 per cent.

4. According to Kissling's estimations, with which those given above coincide, the amount of ash should not be much above 3 per cent., and the amount of water not above 15 per cent.

#### *The Estimation of Cane Sugar by Inversion.* Böhm. Zeits. f. Zuckerind. 13, 559.

Working by Herzfeld's method, Herls found the rotatory power of a cane-sugar solution reading + 100 before inversion, to be - 33.3° after inversion. Croydt's method always gives a lower value, owing to the destructive action of the hydrochloric acid on the sugar. The addition of various salts (5.2-10 parts of potassium nitrate, sodium acetate, and a mixture of these with potassium sulphate and chloride to every 100 parts of sugar) generally increases the levo-reading (up to - 33.69°), but acetates diminish it (- 32.86°). According to Clerget, the levo-reading diminishes by 0.5° for every 1° C. increase of temperature. This does not hold good for all concentrations. Thus, for a solution reading + 50° it is 0.48°, and for one reading + 100 it is 0.51°. Practically these variations are of no consequence. For clarifying purposes, basic lead nitrate is recommended, which is formed in the sugar solution itself by the addition of lead nitrate, followed by potassium hydrate. These additions raise the levo-reading to - 33.5 at 20° C. When working in other respects by Herzfeld's

method, the cane sugar may be calculated by the following formula:—

$$Z = \frac{100S}{1.035 - 0.5t};$$

If raffinose be present the formulae are—

$$Z = \frac{0.5182 P + s}{0.8532}; \quad R = \frac{P - Z}{1.85}; \quad \text{at } 20^\circ \text{ C.}$$

Z = percentage of sucrose. P = polarisation before inversion.  
R = percentage of raffinose. s = polarisation after inversion.  
S = change of reading produced by inversion. t = temperature.

If the temperature of observation be not 20° C. the following formula must be employed:—

$$Z = \frac{r + 0.0015 t}{(r + i) - 0.0035 t}$$

r = reading of raffinose after inversion. i = For each degree  
t = reading of cane sugar after inversion) original polarisation.

$$\text{At } 6^\circ \text{ C. :— } r = 0.1882 \\ i = 0.435.$$

—H. T. P.

#### *The Estimation of Cane Sugar in Presence of considerable Quantities of Raffinose and Invert Sugar.* Wortman. Zeits. f. Zuckerind. 29, 767.

Compared at 20° C. with cane sugar, the rotatory power of raffinose is 1.85; of inverted raffinose, 0.9598; of inverted cane sugar, 0.3266; and of invert sugar, 0.3103. Calling P the direct polarisation, P<sup>i</sup> the polarisation after inversion, and N =  $\frac{C \times 47}{q}$  the approximate percentage of invert sugar (q = wt. of substance taken for analysis; 47 = the average factor of Meissl's tables), then—

$$P = S + 1.85 R - 0.3103 N \quad (1)$$

$$P^i = -0.3266 S + 0.9598 R - 0.3103 N \quad (2)$$

From these equations it follows that—

$$S = \frac{0.9598 P - 1.85 P^i - 0.277 N}{1.5048};$$

$$R = \frac{P - S + 0.3103 N}{1.85};$$

P = 1.85 R will then represent the sum of the readings due to invert sugar and raffinose. From this number Meissl's factor, and consequently the correct percentage of invert sugar may be derived. Substituting this value for N in the above equations, the real percentages of saccharose and raffinose are obtained. A mixture was prepared containing 46 per cent. of cane sugar, 3 per cent. of raffinose, and 4 per cent. of invert sugar. On analysis, the following numbers were obtained:—Cane sugar, 46.004 per cent.; raffinose, 2.993 per cent.; invert sugar, 4.02 per cent.—H. T. P.

*On the Estimation of Sugar and on Polarimetric Observations in Sweet Wines.* A. Bornträger. Zeits. f. angew. Chem. 1889, 477—486, 505—508, and 538—545.

The saccharine matter in sweet wines is composed of varying quantities of dextrose and levulose, and a means of accurately determining the relative quantities of these two sugars cannot be said to be established. The present extensive article forms an inquiry into the modifications recommended for adoption by various investigators, the basis of all the methods being titration with Fehling's solution and observation of the rotation shown by the polariscope. The author recommends the following treatment:—The wine is exactly neutralised with caustic alkali, and heated on the water-bath to drive off alcohol, allowed to cool in a flask, treated with a moderate quantity of lead acetate, and after dilution to the original volume with water, is filtered. The filtrate must be neutral or, if alkaline, must be carefully neutralised, and after standing for one day it is fit for observation in the polariscope and for titration by the Fehling-Soxhlet method.

The article is chiefly devoted to a description of experiments which show the necessity for adherence to the instructions given by the author as above. The influence of temperature and concentration of solution in the polarimetric observations receive special attention. If alkalinity of the wine during evaporation be avoided, the sugars present undergo no change, whilst an evaporation sufficient to drive off the alcohol is indispensable. For sweet wines a dilution to the original volume is sufficient, and as the action of lead acetate is intensified if the free acid be first neutralised, a moderate quantity of that reagent will be found to produce a sufficiently clarified solution for observation in a 200 mm. tube with all wines, except a few deeply coloured Malaga wines, in which case a shorter tube must be used.—G. H. B.

*Comparative Estimations of the Fat in Milk by Different Methods and in Different Conditions of the Milk.* J. Klein. Chem. Zeit. Rep. 13, 284—285.

In continuation of his previous experiments (Chem. Zeit. Rep. 12, 290 and 309), in which he found that Adams' method for the determination of milk fat yielded higher results than the sand or gypsum method, the author describes some comparative results obtained by Adams' and Rose's methods. The milk was examined when fresh, sour, and treated with borax. The results obtained show a close agreement between the two methods in the case of fresh and sour milk. Considerable differences occurred in two out of six analyses, when borax had been added. Estimations of fat were also made by the gypsum method, the results being compared with those got by Adams' process. It appears that even after 10 hours' extraction with ether, the results obtained by the gypsum method are distinctly lower than those got by the second method. Half an hour's extraction with ether serves to remove all the milk fat from the strip of paper employed in Adams' process. The paper strips are, previously to being used, freed from all fatty and resinous bodies by extraction with boiling alcohol. One hour's extraction is more than sufficient for this purpose. When ignited abestos was substituted for the paper strips, the results obtained were somewhat irregular. Assuming the results obtained by Adams' method to be correct, the author finds that the average error of the numbers obtained by Soxhlet's and the gypsum methods is 0.11 per cent. The author therefore holds to his former assertion that "all gravimetric determinations of milk fat made by the methods hitherto in use are low by 0.1 to 0.15 per cent."—H. T. P.

*International Chemical Congress at Paris.* July 30—August 3, 1889. Chem. Zeit. 13, 1391—1393.

### Agricultural Section.

#### I. Analysis of soils:

(a.) Separation of fine sand from clay:—Schloesing's method is recommended without modification. 10 grms. of soil and 2 litres of water are taken and allowed to stand 24 hours. Analyses performed under the same conditions are not exact, but they are sufficiently comparable for all practical purposes.

(b.) Determination of nitrogen:—The soda-lime method gives sufficiently good results; the amount due to nitrates may be left out of account by reason of the exceeding smallness of the quantities present. Kjeldahl's method gives results very slightly higher than the above.

(c.) Determination of nitrates:—The method of Schloesing is recommended, the nitric oxide being collected over mercury and not over water.

(d.) Determination of ammoniacal nitrogen. In this connexion two questions arise, viz.:—Should the determination be made with the soil directly, or with a solution? Should an acid be used? The Congress considers that the soil should be treated with a very slight excess of a weak acid, a sufficient quantity being used to decompose the whole of the calcium carbonate. The determination is then made with the solution. If determination directly from the soil be attempted, it is found that the quantity of ammonia cannot really be ascertained on account of the action of the alkalis on the organic substances contained in the soil.

(e.) Is there any means of ascertaining what percentage of the total phosphoric acid can be assimilated? It is considered in the first place that such a question has little practical interest, and, furthermore, that such a determination is not possible. Phosphate of iron is dissolved to a very considerable extent by treatment of the soil with acetic acid, owing to its solubility in organic iron salts. At the same time, the phosphoric acid of iron phosphate is of service to vegetation, but its assimilation is not easy.

(f.) Determination of potassium:—According to experiments of Schloesing, weak acids (e.g. 0.05—0.1 per cent. nitric acid) extract from soils a quantity of potash, gradually increasing for 3—4 hours; concentrated acids now extract a further quantity, and after this a third lot may be extracted by hydrofluoric acid. The potash seems then to exist in three forms: (1) as silicates difficultly acted on and of little interest to the agriculturist; (2) as more basic silicates, which are decomposed by concentrated acids and which furnish to vegetation a certain quantity of potash; and (3) in a form easily soluble in weak acids, and which can be easily assimilated by plants. It is therefore proposed to examine soils for potash by treating with boiling *aqua regia* until the remaining sand is perfectly white.

(g.) Determination of calcium:—The calcium, useful to vegetation, exists as carbonate, but calcium in other forms exists, and is useful as neutralising the acids of the soil. It is therefore important to distinguish these two forms in which calcium may exist. Total calcium may be determined by the usual methods in the solution obtained for potash determination; carbonate (in powdered form) may be determined in Mondesir's apparatus by using tartaric acid, or total carbonate (powdered and conglomerate) by using hydrochloric acid.

For the potash determination soils should be passed through a sieve having 60 meshes to the inch; decomposition is then complete in two hours; whereas, if a sieve of only 10 meshes to the inch be used (as Gasparin suggests), 12 hours are necessary for decomposition. For the nitrogen determination the soil should be as fine as possible. In every case drying at 100° should be carried out.

#### II. Analysis of manures:

(a.) Determination of nitrogen contained as ammonia, nitrates, and organic:—Total nitrogen may be determined by Dumas' method with copper oxide, and the nitrate nitrogen by Schloesing's method, collecting the nitric oxide over mercury. This latter may also be determined by treating with lime and 50 per cent. alcohol, whereby sulphuric acid, phosphoric acid, silica, &c. are obtained in

the residue, and the nitrate in alcoholic solution; by then evaporating this solution and igniting with ammonium chloride the nitrates are converted into chlorides; the chlorine is then determined, and from this (diminished by the original chlorine in the sample), the nitrates may very simply be calculated. For determination of ammoniacal nitrogen the nitric acid is decomposed by means of ferrous chloride and hydrochloric acid; the ammonia may then be displaced by magnesia. Organic nitrogen may be ascertained in the residue from the two preceding operations by means of soda-lime. After freeing from nitrate nitrogen the Kjeldahl process may be used.

(b.) Distinction of manures according to their source: natural phosphates, slags, dried blood, horn, leather, &c.—The complete solution of this problem is considered of little practical worth, and in some cases it is extremely difficult.

### III. Analysis of fodder:

(a.) Separation and determination of so-called fatty substances and resins:—This may be done by extraction with ether. In special cases such as ensilage, where the fermentation has produced a considerable quantity of lactic acid, which is also soluble in ether, the extract should, before weighing, be washed with water.

(b.) Non-nitrogenous extractive substances are ascertained by difference, being considered as the total of substances not directly determinable.

(c.) Determination of nutritious nitrogenous compounds:—It is not sufficient to determine, as is often done, total nitrogen and calculate this to albuminoids. By doing this, ammonia, nitrates, &c., are all taken as albuminoids. Only such nitrogenous compounds as are insoluble in dilute acetic acid are to be looked upon as nutritious.

(d.) As to tabulation of results, it is considered that these should be given in two forms: (1) on undried; (2) on dried stuff. If two different kinds of fodder are to be compared, they should be compared after being dried; if, however, the value of a fodder is simply required, this should be estimated on the sample in the condition in which it is to be used. Congress considers the following tabulation desirable:—

Moisture.	
Nutritious nitrogenous substances.	
Non-nutritious nitrogenous substances.	
Carbohydrates, &c.	<ul style="list-style-type: none"> <li>{ Fatty substances.</li> <li>{ Starchy substances.</li> <li>{ Sugars.</li> <li>{ Cellulose.</li> <li>{ Non-nitrogenous extractive substances.</li> </ul>
Mineral matter	<ul style="list-style-type: none"> <li>{ Phosphoric acid.</li> <li>{ Other mineral matter.</li> </ul>

### Pharmaceutical Section.

Sulphate of quinine: It is considered advisable that a determination of the sulphuric acid be made, and also a polarimetric examination.

Cinchona bark:—An accurate and practicable method of extraction and separation of the various alkaloids is desirable, and a committee of investigation has been appointed.

Opium:—Chiefly two methods are used for determination of opium: (a) by ammonium chloride; (b) by alcohol and ammonia. In the first method the ammonium chloride should be reduced in quantity as far as possible, owing to the solubility of morphine therein; in the second method the amount of alcohol and ammonia should be kept as low as possible. As pure morphine is obtained in each case, the solubility of this latter in dilute caustic potash ought to be known. It is also desirable to fix a minimum valuation for opium extract. A commission was appointed to inquire into the question.

Chloroform:—Seeing that chloroform keeps better when mixed with alcohol, it is desirable to fix the amount of alcohol which may be added, and to ascertain methods for the estimation of the alcohol added.

Phenol and salicylic acid:—Accurate determination of the chief physical constants is desirable, as well as an alkalimetric method of examining salicylic acid, which is often mixed with higher homologous acids.

Analgesine:—A commission has been appointed to examine its physical constants and chief reactions.—T. L. B.

### Estimation of Formaldehyde by Titration with Ammonia.

W. Eschweiler. Ber. 22, 1929—1930.

The author finds that by titrating with litmus as indicator in place of methyl orange or cochineal, the compound hexamethylenamine which is formed has a neutral reaction, and that one drop of acid colours the solutions red. The same is the case with phenolphthalein. With methyl orange, cochineal, Congo red, and tropoline as indicators, the mono acid compound of hexamethylenamine has a neutral reaction, so that in this case six molecules of formaldehyde appear to combine with three in place of four molecules of ammonia. The author further finds that in order to produce the compound hexamethylenamine the solution of formaldehyde and ammonia must be heated for one hour to 100°—J. B. C.

### ERRATUM.

This Journal, 1889, 902, at the foot of table, for "Saponification equivalents" read "Saponification value."

## New Books.

TECHNISCH-CHEMISCHES JAHRBUCH, 1888—1889. Ein Bericht über die Fortschritte auf dem Gebiete der CHEMISCHEN TECHNOLOGIE, vom April 1888 bis April 1889. Herausgegeben von DR. RUDOLF BREDERMANN, 11<sup>ter</sup> Jahrgang. Berlin: W. Carl Heymann's Verlag, 1890. London: H. Grevel & Co., 33, King Street, Covent Garden, E.C.

Octavo volume strongly bound in cloth and gilt-lettered. It contains Preface, Table of Contents, List of Abbreviated Titles of Works referred to in the text, 614 pages of Subject-Matter, with which are interspersed 263 wood engravings. In the pages enumerated is included a review of New Books which have appeared during the session 1888-89, arranged as works on Physics, Chemistry, Chemical Technology, Mineralogy, Geology, and Botany, and works on miscellaneous subjects. There is also a carefully arranged Index of Names of Authors and another of Subject-Matter.

The arrangement of the Subject-Matter is as follows:—I. Eisen. II. Alkalimetalle, Magnesium, und Aluminium III. Gold und Silber. IV. Kupfer. V. Blei. VI. Zink. VII. Zinn. VIII. Nickel und Kobalt. IX. Chrom und Mangan. X. Antimon, Arsen, Quecksilber, und Platin. XI. Chlor, Salzsäure, Brom. XII. Schwefel, &c. XIII. Sauerstoff, Wasserstoff, &c. XIV. Soda. XV. Kaliumverbindungen. XVI. Ammoniak. XVII. Alkalische Erden. XVIII. Thonerde. XIX. Glas. XX. Thonwaaren. XXI. Cement. XXII. Künstliche Steine. XXIII. Explosivstoffe. XXIV. Leuchtstoffe. XXV. Heizstoffe. XXVI. Zucker. XXVII. Stärke und Stärkezucker. XXVIII. Wein. XXIX. Bier. XXX. Spiritus. XXXI. Fette, Harze, Seifen, &c.

XXXII. Wasser. XXXIII. Nahrungsmittel. XXXIV. Düngemittel, Abfälle, Disinfection. XXXV. Gerberei. XXXVI. Leim. XXXVII. Organische Säuren. XXXVIII. Alkaloide. XXXIX. Farbstoffe. XL. Gespinnstfasern. XLI. Papier. XLII. Photographie. XLIII. Apparate. XLIV. Bücherschau.

A TEXT-BOOK OF ASSAYING for the use of those connected with Mines. By C. BERINGER, F.C.S., F.I.C., late Chief Assayer to the Rio Tinto Copper Co., London, and J. J. BERINGER, F.C.S., F.I.C., Lecturer to the Mining Assoc. and Inst. of Cornwall, &c. London: Chas. Griffin & Co., Exeter Street, Strand. 1889.

This is an 8vo volume, bound in cloth, and containing 385 pages of Subject-Matter and an Appendix of six pages, followed by an Alphabetical Index; with the text are interspersed 82 wood engravings.

In their preface the authors state that "Under the more important methods they have given the results of a series of experiments showing the effects of varying conditions on the accuracy of the process." "Such experiments are often made by the assayer, but seldom recorded." Then they add, "Statements like those generally made—that 'this or that substance interferes'—are insufficient, 'it is necessary to know under what conditions and to what extent.'"

The authors consider "the practice of naming a process after its discoverer, which has recently much developed, is proving objectionable, and that though we may speak of a Bunsen's burner or a Liebig's condenser, yet when matters are pushed so far that the chemist is directed to 'Finkenerise,' a residue, or to use the 'Reichert-Meißl-Wollny process,' it is time to stop." Hence they have omitted to carry out such an association in referring to the processes they cite.

The work is subdivided as follows:—PART I.—I. Introductory. II. Methods of Assaying.—Dry Gravimetric Methods. III. Wet Gravimetric Methods. IV. Volumetric Assays. V. Weighing and Measuring. VI. Reagents. VII. Formulae, Equations, &c. VIII. Specific Gravity. PART II.—IX. Silver, Gold, Platinum, Mercury. X. Copper, Lead, Thallium, Bismuth, Antimony. XI. Iron, Nickel, Cobalt, Zinc, Cadmium. XII. Tin, Tungsten, Titanium. XIII. Manganese, Chromium, &c. XIV. Earths, Alkaline Earths, Alkalis. PART III.—XV. Oxygen and Oxides.—The Halogens. XVI. Sulphur and Sulphates. XVII. Arsenic, Phosphorus, Nitrogen. XVIII. Silicon, Carbon, Boron. APPENDIX.—Various tables of Atomic Weights and other Constants, Thermometric Scales, Strengths of Acids, and Ammonia, with Corresponding Specific Gravities.

The price of the work is 10s. 6d.

PROMETHEUS. ILLUSTRIRTE WOCHENSCHRIFT ÜBER DIE FORTSCHRITTE DER ANGEWANDTEN NATURWISSENSCHAFTEN. Herausgegeben von DR. OTTO N. WITT. Berlin: S.W. Rudolf Mückenberger. London: H. Grevel, 23, King Street, Covent Garden.

THIS new and elegantly arranged Journal of general and applied science made its first appearance in 1889. Judging from the first ten numbers that have appeared, it would seem, put briefly, that the leading idea running through the compilation is the popularisation of science by bringing it in contact with all the current events of the day in which it plays a part. For example, in the opening issue, the first article is one on "Brown Coal"; the second, illustrated with excellent engravings, on the "New Double-Screw Steamer of the Hamburg and American Steamship Company"; the third, on "New Metals and Alloys"; and the fourth, on the new "Automatic Electric Light Producer" of the Great Western Railway Company's service of trains (illustrated). In subsequent numbers many articles relating to Chemical Manufactures and Industry appear, and they are treated in all cases so as to combine accuracy, elegance of style, interesting reading, and admirable illustration. The Journal is a weekly one and the price is 3 marks (3s.) per quarter.

CHEMISCH-TECHNISCHE ANALYSE. Handbuch der Analytischen Untersuchungen zur Beaufsichtigung des Chemischen Grossbetriebes und zum Unterrichte. Herausgegeben von Dr. JULIUS POST, Professor an der Technischen Hochschule zu Hannover. Zweite vermehrte und verbesserte Auflage. Erster Band, Vierte Lieferung. Zweiter Band, Erste Lieferung. 1890. Braunschweig: Druck und Verlag von Friedrich Vieweg und Sohn. London: H. Grevel and Co., 33, King Street, Covent Garden.

PART IV. of the first volume of this work with Part I. of the second volume have just made their appearance. For notices of the earlier issues of Vol. I. (see this Journal, 1888, 872). The prices of the two parts now noticed are, Part IV., 5s. 6d.; and Part I. of Vol. II., 3s.

PART IV. (conclusion of Vol. I.).—This volume treats of Inorganic Acids, Alkalis and their salts, and Chloride of Lime, and is mainly devoted to the products of the Sulphuric Acid and Alkali manufacture with the allied industries. It contains 195 pages of subject-matter, and is illustrated with numerous excellent wood engravings.

As regards the distribution of the text, 56 pages are devoted to Sulphuric Acid and Sulphates; 3 to Nitric Acid; 15 to various Salts and the Stassfurt Industry; 4 to Ammonia and its Salts; 7 to Hydrochloric Acid; 26 to Soda and its Salts; 4 to the Regeneration of Sulphur from Alkali Waste; 9 to the Potassium Salts and Potash; 13 to Chloride of Lime, and 23 to Mannures.

PART I., VOL. II.—This is a treatise on (1) Lime, Gypsum, and Cements; (2.) Porcelain and Earthenware, and (3.) Glass. To Group 1, about 30 pages are devoted; to Group 2, 50 pages, and to Group 3, 22 pages.

A HANDBOOK OF QUANTITATIVE ANALYSIS by JOHN MILLS and BARKER NORTH. London: Chapman and Hall, Ltd., Agents to the Science and Art Department. 1889.

SMALL 8vo. volume, bound in cloth, containing Preface, Table of Contents, 203 pages of Subject-Matter, an Appendix of 5 pages, and an Alphabetical Index.

The scope of the book is stated in the Preface to be such as to meet the requirements of students entering for the Honours Examination in Inorganic and Organic Chemistry of the Science and Art Department. It is also stated to be sufficient for the Associateship of the Institute of Chemistry, the B.Sc. and M.B. Practical Examinations of the University of London.

The work is classified as follows:—I. Introduction. II. Simple Examples of Gravimetric Analysis. III. Simple Examples in Volumetric Analysis. IV. Simple Examples of Quantitative Separation. V. Analysis of Alloys. VI. Analysis of Minerals, Ores, &c. VII. Analysis of Commercial Products. VIII. Assaying by Cupellation. IX. Analysis of Water. X. Gas Analysis. XI. Ultimate Organic Analysis. Appendix, with useful explanation and description of Filter Pumps; Modes of Preserving Platinum and Silver Vessels; Mending Platinum Vessels; Cleaning Platinum Vessels; Recovery of Platinum and Silver Residues, &c.

The text is illustrated with 31 wood engravings. The price of the book is 3s. 6d.

## Trade Report.

### TARIFF CHANGES AND CUSTOMS REGULATIONS.

#### SWITZERLAND.

##### *Classification of Bauxite in Customs Tariff.*

Bauxite (mixture of hydrated alumina, hydrated oxide of iron, and silicic acid), raw or ground.—Category 160. Duty free.—*Board of Trade Journal.*

#### AUSTRIA-HUNGARY.

##### *Customs Classification of Hydrosulphite of Indigo.*

According to the *Moniteur Belge* for the 23rd November, the Austro-Hungarian Customs authorities have decided that the substance called *cure d'hydrosulfite* or hydrosulphite of indigo is classified under Category 324 of the tariff, and pays a duty of 4 florins per 100 kilogrammes.—*Ibid.*

#### BULGARIA.

##### *Provisional Commercial Arrangement with United Kingdom.*

The following is a copy of a notice issued by the Foreign Office on the 31st December last:—

An arrangement has been negotiated by Mr. O'Connor, Her Majesty's Agent and Consul-General at Sofia, by which British goods will be admitted into Bulgaria on and after the 1st January 1890 upon payment of Customs duties at the rate of 8 per cent. *ad valorem*.

Alcohol, gunpowder, salt, and tobacco are not included in this arrangement, but these goods of British origin will receive most favoured nation treatment.—*Ibid.*

### EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

#### SULPHUR MINING IN SICILY.

The following information respecting sulphur mining in Sicily is extracted from the last report of the United States Consul at Catania:—

"The mine district in Sicily comprises the provinces of Catania, Caltanissetta, Girgenti, and the commune of Lercara, in the province of Palermo. There are in all 567 mines, 191 of which are closed, on account of being remote from the railway lines, and carrying the mineral on the back of mules or donkeys does not pay to work them.

"On the commercial point of view I may give some summary details on the working and on the method of smelting in use, whilst on the scientific point the matter has been splendidly treated by illustrious geologists of Italy, Great Britain, Germany, and France.

"The interior of a mine is carried with pillars and vaults (here commonly called 'colonne, pasture, and tetti') in the same manner as a coal mine. There you see the same galleries, the same portable underground rails, the same small waggons by means of which the rock (brimstone ore) is carried to the vertical or inclined shaft and through this by means of steam engines is lifted up and piled on the open soil.

"The galleries in the mines are sustained by pillars of rocks superposed one upon the other, and there are galleries one under the other until the stratum is exhausted. When the mine has surpassed the depth of 40 metres, water is generally found, and the hauling engine is used also for pumping. The air of the interior of a mine is generally impregnated with gases, often inflammable, and the first care

in opening a new mine is in getting a current of air. This is obtained by opening a second pit-hole communicating with the first.

"Safety-lamps have been introduced everywhere in order to prevent explosion. By a recent law every mine is to be supervised by a mineralogical master (*capominatore*) in order to prevent disasters, and to hold the fitters, owners, or contractors responsible for same, or for accidents happening to workmen when labouring. On the other side, owners or fitters, by means of a small premium paid to the 'Cassa Nazionale sugli Infortuni' (National Insurance Bank) against accidents happening to labourers are able to stand such losses. In those mines where there are no engines the mineral is carried in bags by boys on stairs on the inclined shaft up to the open soil. When the engines are in use it is hoisted up in waggons.

"The melting of brimstone is only allowed by the Italian Government from the 24th of June till the end of October, as the evaporating acids injure the grain fields.

The smelting process is very simple and takes place at mines. No machinery, no engines are to be seen; the ore is simply put in kilns (*calcaroni*) of the capacity of from 100 to 1,000 cubic metres, filled with lumps of ore and covered with earth, in order to prevent excessive evaporation. The mass is then lighted on the highest point of the inclined line at the bottom of the kiln. When fire has made a good progress in the kiln it is covered completely, and slow internal combustion commences, a good quantity of the mineral acting as fuel for heating and smelting the whole mass. In about five days a hole is made at the lowest point of the inclined bottom of the kiln, and the sulphur flows out in a liquid state into small wooden forms of the capacity of about 65 kilogrammes, which are filled continuously one day after the other until the kiln has ceased to flow. The liquid brimstone is then kept for about three hours in the forms, just sufficient time for cooling and changing into a solid state. In cooling, the sulphur contracts, and falls easily out of the forms. It is then ready to be sent to the nearest harbour for shipping. It is graded into seven different qualities, from the finest yellow to the darkest brown, and denominated: Lieata, first quality; best, second unmixed; good, second unmixed; current, second unmixed; best, third unmixed; good, third unmixed; current, third unmixed. When the ore is very rich, steam is used instead of fuel, and different systems, covered by patents, are adopted. The work is paid by cubic measure of mineral (ore) brought out of the mine. The work in the mine is considered unwholesome; as proof thereof it is to be remarked that in those provinces of Sicily where mines are abundant, the greatest number of young men are deformed and unfit for military service.

"The number of workmen employed in a mine is, according to the importance of the same, from 4 to 400 men and boys, working, on an average, eight hours, and earning about 3 lire for men and 1½ lire for boys (1 lira = 9 *d.*). The miner, with his small earning to support his family, has to live very economically. Miners pay no personal taxes except the commune tax, which is included in the price of victuals. Every mine has a gang of boys to carry the ore out of the mine where the work is not done by machinery.

"In the last years the prices of sulphur have gone down sensibly, owing to the adoption of steam-engines in the mines, to the opening of the railroads, which have reduced the cost of transportation to the harbours, once so costly because done by carts, mules, and donkeys, and to the superabundance of production in comparison with consumption and export.

"I think prices will keep low for many years, unless speculation on the markets should bring a fictitious rise of a short duration. It is my belief that few, if any, countries can compete in cheapness of hand-labour with the Italian workmen, well known everywhere for their sobriety.

"The refinement of brimstone is made with different systems (patented), but on the same principle. Brimstone is put into retorts and through a small fire, is evaporated, and condensed in cooling ovens. The grinding is done in different ways, all kept secret. Rolling, crushing, or vertical stone-mills are used; but I should never advise American buyers to import ground brimstone, as very often

it is adulterated with sundry stuffs, such as chalk, earth, strontia, &c., and dyed with chromate of yellow. Many sulphur mines have been worked in Sicily by foreigners, but very few of these have succeeded in getting any profit.

"Sicilians work the mines very economically, and only for large and rich mines steam-engines are used, whilst foreigners begin always with many expenses, without ascertaining the thickness and extent of the stratum. Owners very seldom sell their mines, except at exorbitant prices. The general usage is to lease the mine to fitters (*gabellotti*), getting from 10 to 40 per. cent. of the yield of brimstone during the time of the lease, which runs from 2 to 40 years. On the mines there is only one tax, the land tax. This is paid to the Government, not on the value of the over-soil, but on that of the under-soil, according to the formed working mine."—*Ibid.*

#### THE CAPE COLONY.

The statistical returns show that the trade of the Cape Colony has increased considerably in the year 1888. The prosperity of the Cape Colony and Natal has been greatly stimulated by the opening up of the Transvaal goldfields, with its accompanying large influx of foreign population. Kimberley, with its diamond mines, saved Cape Town; and the Transvaal, with its gold mines, will save the Colony. The rapid advancement of South African wealth and commercial prosperity, and in the development of various manufacturing industries, hinges entirely on the prosperity of the mines of the Transvaal. Any hindrance or check to them would react most fatally on colonial prosperity.

The declared value of pharmaceutical goods imported into Cape Colony increased from 59,595*l.* in 1887, to 76,764*l.* in 1888; oilman's stores, from 140,988*l.* to 162,110*l.*; paints, from 18,312*l.* to 20,494*l.* The exports of aloes grew from 152,367 lb. to 657,785 lb.—*Chemist and Druggist*.

#### CHINA.

##### *Cassia Lignea.*

The principal cassia-growing district in China is Loting, in the province of Kwang-tong, and a good deal is also produced in the province of Kwang-si. About 80,000 piculs of cassia are exported yearly from Canton and Pakhoi. Until 1887 the trade was a fairly prosperous one, but since then the profits have fallen off, so far as the two centres named are concerned, because the junks carry the cassia at a very low rate from the growing districts directly to Hong Kong, and tranship it there in the European steamers, whereby the spice is less liable to deterioration than when it is handled more frequently.

##### *Musk.*

The exports of musk from Shanghai during the last two years have been as follows:—

	1888.	1887.
To London .....	Catties, 375	Catties, 602
Mar-elles .....	908	770
New York .....	575	285
Hamburgh .....	119	71
	2,103	1,728

About 75 per cent. of this was Tonquin, 20 per cent. Yunnan, and 5 per cent. Cabardine musk. Yunnan musk is only brought to market in small quantities nowadays.

##### *Galls.*

The most noteworthy feature of the trade in nutgalls in 1888 was the increase of the shipments to Germany from 6,300 piculs in 1887 to 13,438 piculs in 1888, and the decrease of the exports to London, which were 12,680 piculs in 1887, and only 9,094 piculs in 1888.—*Ibid.*

#### GUATEMALA.

##### *Drug Cultivation.*

The Government is offering a good many inducements to agriculturists to take up the cultivation of economic plants, including many varieties of drugs. Anyone desirous of cultivating sarsaparilla, rubber, or cacao, and not having land for the purpose, can, on requisition, be put in possession of a suitable lot. The following rewards are offered to agriculturists who at the end of eight years can show healthy plantations of cinchona (*calisaya* or *succirabra*):—154*l.* for 1,000 plants eight years old to the first cultivator, 77*l.* to the second, 36*l.* 10*s.* to the third, and 15*l.* 10*s.* to all others. A premium of 4*l.* for a term of three years is given for every 150*l.* of indigo grown and made in the country, and at the end of ten years after commencing the cultivation a reward of 11*l.* 10*s.* for every thousand gum trees planted out, of five years old.

##### *Cochineal.*

The industry of cochineal raising has almost entirely disappeared from the country. For thirty years cochineal was the principal article of export, but now what little is grown is used for native consumption.

##### *Coca.*

A quantity of coca seed was imported from Peru in 1888, for distribution among the people in a suitable zone for its growth; but the result was unsatisfactory, from the bad quality of the seed, and fresh means are being taken to extend the cultivation of this plant.

##### *Vanilla, Cinchona, &c.*

The vanilla plant grows wild on the mountains all over the country. The quality of the vanilla is good, but though it figures as an export it is not cultivated for that purpose. Peruvian bark has proved a failure, and the cost of introducing the tree has been practically lost. Indigo works are subsiding in the country; a few still exist in the east, but though means are taken to encourage them, only 93*l.* of indigo was exported in 1888.—*Ibid.*

#### JAPAN.

##### *Camphor Adulteration.*

In camphor the quantity exported from Nagasaki was some 300,000 lb. less than the previous year, the figures being:—1887, 2,008,028 lb., value 38,200 *dols.*; 1888, 1,689,452 lb., value 39,276 *dols.* Prices ruled high, but the trade is being gradually injured by the systematic adulteration carried on. Owing to the higher prices ruling in 1888, salt, rice, flour, and water were used in considerable quantities, in some cases amounting to nearly 40 per cent. of the whole.

##### *Drug Imports.*

The imports of foreign drugs into Nagasaki increased from 1,823*l.* in 1887 to 6,827*l.* in 1888.

##### *The Trade for 1888.*

The foreign trade of Japan for 1888 shows a far greater expansion than has been obtained in any previous year, the figures being:—

	1888.	1887.
Imports .....	£ 11,395,353	£ 8,905,320
Exports .....	10,667,266	8,184,322

By far the greater portion of this increase falls to the United Kingdom. The following figures are of interest to the drug trade:—

*Imports.*

	1888.	1887.
	£	£
Druzs .....	282,540	256,949
Dyes and paints .....	117,750	110,315
Glassware .....	56,965	42,719
Scientific instruments .....	70,915	47,491

*Exports.*

	1888.	1887.
Camphor .....	Tons 2,549	3,816
Japan wax .....	" 1,495	1,805
Antimony .....	" 1,300	2,026
Drugs .....	Value £ 29,399	12,743

—*Ibid.**Exports in 1888.*

	England.	Germany.	America.	Austria.	France.	Other Countries.	Total Value.
Antimony.....	Sacks 7,961	..	..	..	..	..	£ 28,659
Chrome.....	Tons ..	..	2,480	..	152	..	19,528
Sponges .....	Bales, sacks, cases 6,493	..	..	3,978	579	497	83,138
Galls.....	Sacks 998	604	10	209	174	579	19,296
Gum.....	Cases 73	..	140	86	316	82	4,182
Mastic .....	" 41	..	..	..	..	..	1,230
Olive oil .....	Barrels 128	..	1,128	276	654	225	24,688
Opium.....	Cases 719	4	1,459	55	239	552	242,249
Liquorice root .....	Bales 7,346	..	47,859	..	2,098	10	50,135
" paste .....	Cases 5,859	..	..	189	..	187	19,923

—*Ibid.*

## UNITED STATES OF COLOMBIA.

*Drugs and Patents.*

French and American patent medicines have a very large sale at Cúcuta, as drugs are much needed, and the medical profession is largely in the hands of quacks. Drugs and chemicals are also paying articles of import. The excessive and irrational duties almost preclude the importation of many foreign articles; toilet soaps, tooth-brushes, india-rubber goods, &c., for instance, are excessively dear.—*Ibid.*

## VENEZUELA.

*Copaiba.*

The copaiba tree is so universally distributed throughout the forest in the region of which Maracaibo is the principal port, that it alone should produce a revenue sufficient to sustain the population of the province.

*Copaiba Balsam.*

From Ciudad Bolívar, one of the principal trading centres in Venezuela, it is reported that the advance in the price of copaiba balsam has caused much greater attention to be paid to the collection of this article than was the case before. During the year 1888 17,488 kilos. of this article were exported.

*Touquin Beans.*

The export of Touquin beans has also increased, having been 21,772 kilos. A large part of the 1888 crop was destroyed by the excessive heat.—*Ibid.*

## TURKEY IN EUROPE.

*Antimony.*

Three antimony mines have been recently opened in the Salonica district, and, on the whole, are successfully worked—two by British subjects and one by an Austrian company. The ore, of which about 300 tons have already been exported—chiefly to the United Kingdom—is of very good quality, and costs about 10*l.* per ton "F.o.b." at Salonica.—*Ibid.*

## TURKEY IN ASIA.

*The Drug Trade.*

A very large trade in druggists' goods is carried on from Smyrna, as may be seen from the following figures. Of drugs last year the following quantities were imported:—From Great Britain, 1,043 cases; Germany, 57 cases; Austria (Trieste), 624 cases; Belgium, 47 cases; France, 1,545 cases; Italy, 287 cases; other countries, 178 cases; total, 6,988 cases; value 63,904*l.*

## WEST COAST OF AFRICA.

*Export Duties.*

Certain export duties are still kept up in the British colony of Sierra Leone, in the Niger Territories, and in Gambia. In the French and German settlements on that coast, however, there are none, nor in Lagos, the Gold Coast, and Liberia. The principal duties are:—

Articles.	Gambia.	Sierra Leone.	Niger Territories.
	£ s. d.	£ s. d.	£ s. d.

## MEXICO.

*Drug Exports.*

The bulk of the drugs exported from Mexico is shipped to the United States, though from there a large part finds its way to the United Kingdom. The following figures are of interest as showing the comparative value of the exports during the last five years:—

Articles.	Annual Average, Five Years ending June 30, 1884.	Year ending June 30, 1886.	Year ending June 30, 1887.	Weight.
	Dollars.	Dollars.	Dollars.	Tons.
Aloes (essential oil)...	1,576	..	10,121	14.5
Cascarilla.....	..	..	1,264	8.0
Chicle (chewing gum).	73,288	127,906	285,930	570.4
Honey.....	74,559	47,564	35,719	630.8
Indigo.....	64,984	95,269	50,289	34.7
Jalap.....	30,324	19,541	10,926	63.5
Sarsaparilla.....	49,569	95,870	55,669	482.6
Vanilla.....	425,150	419,178	555,113	49.5

The essential oil of aloes is exported from Vera Cruz in about equal proportions to Great Britain and France; the chicle gum, which goes all to the United States, where it has obtained an enormous popularity, lately comes nearly all from Tuxpan, with an occasional shipment from Tampico and other ports. Honey is also shipped to the States from Tuxpan and Tampico. The principal port for indigo is Tonala, but Salina Cruz and Vera Cruz also participate to some extent in the business. About two-thirds of the Mexican indigo are sent to France, and most of the remainder to Germany. As regards sarsaparilla the export figures bear witness to a heavy decline in the output, but with jalap the case is rather the reverse. Of this root more than four-fifths come from Tampico, about one-eighth from Tuxpan, and the inconsiderable residue from Vera Cruz and Matamoros. The United States receive one-half of the root, France a quarter, and the rest goes to England and Germany. Of the Mexican vanilla, which is brought into commerce mostly *via* Tuxpan, and partly through Vera Cruz, nearly all goes to the States, and a little to France.—*Ibid.*

## SIAM.

*Dyeing Materials.*

The export from Bangkok of dye-woods, gamboge, indigo and other materials used in dyes, shows no increase, the fact being that chemical dyes are now rapidly supplanting the vegetable. The smallness of the amount of cutch exported is remarkable. In Burmah this article of jungle produce has risen to a very important item in the export, and there is every reason to believe that there is plenty of cutch in Siam also. It would be worth the while of the Siamese Government to investigate the reasons why more is not made of this source of natural wealth in the country.—*Ibid.*

## SPAIN.

*The Cochineal Industry.*

Cochineal still continues to hold its place as the principal article of export from the Canary Islands. During 1888 the following quantities were shipped:—To England, 220,339 kilos.; France, 132,127 kilos.; Germany, 117,460 kilos.; Spain, 6,912 kilos.; Africa, 5,432 kilos.; total, 482,260 kilos.; equal to 1,048,110 English lb. This trade is gradually declining every year, owing to the unremunerative prices offered in Europe, and endeavours are constantly being directed to the finding of a substitute for this product.

*Sulphate of Copper.*

The application of sulphate of copper has been found to be useless against the mildew, and it is believed in some quarters that this remedy has only a preventive and not a curative character, though others assert that the remedy failed because it was applied too late, and, besides, not only is the unfortunate vine attacked by mildew, but it is also exposed to the ravages of four other phases of destruction, well known to all acquainted with vine-growing.

## GERMANY.

*Profits in Chemical Industry.*

The German chemical industry has been on the whole in a very flourishing condition during the year 1888. According to recently published statistics the number of factories falling under this description has increased from 4,235 in 1887, to 4,464 in 1888, that of the average number of hands employed from 82,211 to 84,315, and the total of the wages paid from 62,710,380 to 65,644,013 m., the average wages of each hand having been 757.13 m. in 1887, and 773 m. in 1888. The dividends declared by the chemical factories carrying on business as limited liability concerns during the last five years have been as follows:—

	1884.	1885.	1886.	1887.	1888.
	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Alkali and heavy chemicals.....	6.8	5.77	5.79	6.02	7.45
Pharmaceutical and fine chemicals.....	13.26	12.63	14.14	16.28	13.81
Coal tar products.....	11.05	7.03	9.94	13.25	15.44
Explosives.....	7.84	10.8	16.46	14.33	15.58
Artificial manures.....	6.21	3.07	2.51	5.32	7.97

The following table shows the proportion of profits of the limited companies during the last five years:—

Year.	No Dividend Declared.	Under 5 per Cent. Dividend.	5 to 10 per Cent. Dividend.	Over 10 per Cent. Dividend.
1884	Per Cent. 25	Per Cent. 23	Per Cent. 33	Per Cent. 19
1885	34	22	28	16
1886	33	24	13	29
1887	33	12	30	20
1888	32.5	16.25	23.25	25

## MISCELLANEOUS TRADE NOTICES.

## TRADE WITH THE BLACK SEA.

The *Deutsches Handels-Archiv* informs its readers that the articles which find the most ready market in the Turkish ports of the Black Sea are Turkey-red cotton thread, cloth stuff, whether wholly or partly of wool, cheap hardware, chemical products, dyes, and beer, the consumption of which is rapidly on the increase. There is room, says the German paper, for a very great development of trade in the Black Sea, and merchants would do well to let themselves be represented by active and capable agents who have made themselves acquainted with the character of Turkish trade and the requirements of the inhabitants.—*Board of Trade Journal.*

## THE DEVELOPMENT OF YUCATAN.

The Belgian Consul at Merida has forwarded to his Government a report on the commercial position of the State of Yucatan, from which we extract the following particulars:—

After a long period of decline and impoverishment, the last two or three years have seen a very remarkable revival of prosperity throughout the State of Yucatan, and in particular in Merida, its capital, and this division of Central America must now be regarded as offering a market to European goods. Merida, which is united to the sea at the port of Progreso by a short line of railway, now contains upwards of 50,000 inhabitants, and publishes 10 newspapers. The principal squares and the Hidalgo Park are lighted with electricity, and a considerable number of fine public buildings have recently given to the city an air of importance. It was the year 1888 in which the condition of Yucatan became to a marked degree ameliorated. The main industry of the country is the manufacture of the textile hemp called henequen, the price of which rose rather suddenly to the unprecedented figure of three piastres the arroba. In consequence, very large commercial transactions were effected in 1888 and 1889 by the capitalists resident in Merida.

The product which occupies the second place after henequen is bluewood or campéchy wood, the amount of which exported in 1889 has greatly exceeded previous returns. The whole import trade of 1888 showed a considerable increase, but the merchants of Europe seem as yet not to have waked up to the idea that a market for their goods has opened up in Yucatan. At present the only countries from which goods are imported into the State are the United States, England, Germany, France, and Spain.—*Ibid.*

## CINCHONA IN MADRAS.

The Calcutta *Englishman* (overland mail) for the 3rd December says:—

"From the report on the Government cinchona plantations in the Nilgeries we gather that 110,162 lb. of bark were taken during the past year; and adding this to the balance on hand from the previous year, there was a total of 254,130 lb., of this 18,350 lb. were disposed of by using 17,300 lb. for the manufacture of febrifuge, and the remainder was sold to the Medical Stores Department. The actual money realised by sale of bark, &c. amounted to Rs. 3,601, while the value of febrifuge supplied free of cost to medical stores was about Rs. 3,000; and that supplied to the Mysore Government Rs. 2,417, making in all a total revenue of about Rs. 9,000. The actual expenditure amounted to Rs. 69,493, so that the Government suffered a clear loss of something over Rs. 60,000 on the working of the cinchona plantations during the past year.—*Ibid.*

## CINCHONA PLANTING.

*Van Romunde. Nederl. Tijdsch. Pharm. Chem. en Toxicol.* 1889, 1, 259.

During the year 1888 the quantity of bark collected in Java was 380,899·5 kilos., of which 1,109 kilos. were used in the country itself, the remainder being sent to Holland. The amount for the first quarter of 1889 was 87,500 kilos.

—T. L. B.

## PRODUCTION OF COBALTFEROUS MATT OR CHEEP IN NEPAL.

Communications have been received at the Board of Trade from the India Office enclosing certain memoranda from the Revenue and Agricultural Department of the Government of India at Simla relating to the production and analysis of a substance called "cheep" which is obtained close by the copper mines in Nepal. The name of the locality is "Kachipatar" Argah Zillah, Sowrobhar, about 80 miles north of Deolha, on the estate of Mr. D. Ricketts.

A sample of this substance was sent to the Director, Geological Survey of India, for analysis, and in a report by the latter he says:—"The sample of cheep has been analysed with the following results:—Loss at 100° C. 0·40; insoluble in acids 0·70; sulphur, 20·41; cobalt, 13·97; iron, 62·82; total, 98·30.

"Cobalt is principally used in the state of oxide for colouring pottery and glass, and 13·97 of the metal is equivalent to 19·69 of oxide. Assuming therefore that the specimen analysed is a fair average sample, the cheep would yield nearly a fifth of its weight of cobalt oxide. It appears from the 'Mineral Resources of the United States' for 1886 (the last available) that 14,215 lb. of cobalt oxide were imported in that year, valued at 22,757 dols., which is at the rate of 717l. per ton. According to Mr. Ricketts's letter of the 23rd January 1888, to your address, the 'cheep' is sold at Kachipatar, the place of production, at Rs. 30 to Rs. 35 per maund, and at Deolha at Rs. 40 to Rs. 50. These prices are equivalent (taking the rupee at 1s. 4d., and 27·22 maunds as equivalent to one ton) to 54l. to 64l., and 73l. to 91l. a ton. As five tons of 'cheep' therefore (containing one ton of cobalt oxide) would be worth at the above prices 270l., 320l., 365l., and 455l., and the cobalt oxide would be worth, after extraction, about 700l., there would appear to be a fair margin to allow of the 'cheep' being exported to England and treated there. That is to say, if it is obtainable in sufficient quantity. The metallurgical treatment of cobalt ores being rather difficult, it does not seem probable that the natives of Nepal are acquainted with any process by which a fairly pure oxide can be obtained.

"In reply to a communication respecting the probable supply of cobaltiferous matt from the Secretary to the Government of India, Foreign Department, Simla, to the President in Nepal, the latter states:—"In reply to your letter asking for a report as to the probable supply of 'cobaltiferous matt,' which would be obtainable if a demand were to arise for the substance among cobalt refiners in England, I have the honour to state that Mr. Ricketts, of Deolha Estate, Gorakhpur, though unable to estimate in figures the quantity that would be procurable if the above contingency were to arise, is of opinion that the supply would, in all probability, increase with the demand, which is at present about 400 maunds annually."—*Board of Trade Journal.*

## INDIA-RUBBER MONOPOLY.

The *Provincia do Para*, a journal of Para, throws some light on the new tax of 20 reis per kilo. laid on india-rubber. It will be remembered that since January 1st that tax is paid, not to the State, nor to the province, but to the Companhia Mercantil. The Governor of the Province of Para received on November 30th a petition signed by numerous commercial men of Para, begging that a tax of 20 reis per kilo. should be laid on india-rubber for a period of five years, and that it should be paid to the Companhia Mercantil "as a compensation for the efforts, and especially for the sacrifices, that company is making to support our market, and to keep up the price of our principal product for exportation, which is threatened with a permanent depreciation of its value, owing to the manœuvres of a group of powerful speculators for the fall, who have, during the last few years, sought to absorb our market almost completely."

The petition also declared that, in supporting the price of india-rubber, the Companhia Mercantil effectually aided in insuring a progressive increase of the public revenue. The Companhia Mercantil on the same day addressed a similar petition to the Governor, and assured him that the company would employ the proceeds of the tax solely to cover any loss that might arise from its operations for supporting the price of india-rubber, and that any balance that might remain would be handed to the State.

Notwithstanding the protests of numerous delegates from the opposition group of commercial men at Para, who had an interview with the Governor, that functionary decreed the levying of the additional tax of 20 reis per kilo., to be paid to the Companhia Mercantil. M. Justo Leido Chermont, Governor of Para, who signed this decree, is, it is stated, a large shareholder and President of the Council of Administration of the Companhia Mercantil. The merchants who protested against the tax have sent a petition to General Deodoro da Fonseca, Chief of the Provisional Government, demanding its abolition, and they seem to be pretty confident that the decree will be repealed and the sums paid by them to the Companhia Mercantil shortly returned to them.—*Standard.*

## THE BRAZILIAN INDIA-RUBBER INDUSTRY.

A newspaper in Providence, U.S.A., where extensive rubber works are established, has received advices from Para stating that the concession recently obtained from the Provincial Government by the Companhia Mercantil de Para, permitting it to levy a duty of 20 reis per pound upon the entire export of Para india-rubber, has been cancelled.—*Standard*.

## RECENT UNITED STATES STATISTICS.

Metals.....	..	Dols. 256,245,103
Mineral substances.....	..	328,914,518
Mineral products, unspecified.....	..	6,500,000
Grand total.....	..	591,659,631

## FERTILISERS.

The importations of kainit during the year aggregated 12,600 tons. This compares with the receipts during the three preceding years as follows:—1888, 17,500 tons; 1887, 6,000 tons; 1886, 16,900 tons. The syndicate price throughout the year has been 10 dols. per ton actual weight, and 9.75 dols. per ton foreign invoice weight.

The importations of muriate of potash during the year aggregated 28,445 tons. This compares with the receipts for the two preceding years as follows:—1888, 27,922 tons; 1887, 17,905 tons. The importations at the port of New York for the three years were respectively 18,030, 16,560 and 9,945 tons. The syndicate price averaged 1.80 dols. per 100 lb.

Early in the year a prominent firm of importers endeavoured to secure the free entry of high-grade sulphate of potash, claiming that the duty enforced upon it practically prohibited its use in this country, and therefore was prejudicial to the interests of importers and consumers. A final decision has not been reached on the subject as yet, and it is expected that when Congress next considers the question of the tariff it will be formally asked to place sulphate of potash upon the free list.

A notable feature of the year was the falling off in the Southern consumption of Northern fertilisers. Acid factories are being established all through the Southern States, and there is certainly no reason why the South should be dependent upon the North for its fertilisers. During 1889 the consumption of acidulated phosphate rock in the South materially increased, but Northern dealers had little or no part in it.

## NITRATE OF SODA.

The shipments to the States were 667,500 bags, against 517,500 the year before; 555,000 in 1887; 522,750 in 1886; and 270,323 in 1885.

The quantity to arrive for Atlantic ports is 320,000 bags, against 221,000 in 1889; 239,000 in 1888; and 238,500 in 1887. The total visible supply is 371,726 bags, against 310,000 in 1889; 301,940 in 1888; and 311,266 in 1887.

The quantity to arrive in Europe is 2,835 in bags, making the visible supply then 4,312,509 bags, against 3,112,000 last year and 2,927,500 in 1888.

The deliveries at San Francisco in 1889 were 80,060 bags, making total deliveries in this country 618,358 bags, against 515,000 in 1888; 534,347 in 1887; and 454,760 in 1886.

In Europe the deliveries were 4,920,000 bags, making total for the world 5,538,358 bags, against 5,227,000 in 1888; 4,164,317 in 1887; 3,522,260 in 1886; and 3,278,686 in 1885.—*Engineering and Mining Journal*.

## EXPORTS OF MINERAL OILS FROM THE UNITED STATES FOR NOVEMBER 1889.

S. G. Brock, Chief of the Bureau of Statistics, submits the following statement of the exports of domestic mineral oils from the United States for the month of November, 1889:—

*Mineral Oils, Crude.*

(Including all natural oils, without regard to gravity.)

	Gallons.	Dols.

## THE COPPER INDUSTRY.

The Spanish Government having recently ordered the Rio Tinto Company to diminish by one-half the quantity of copper ore it was burning near Huelva, on the ground that the smoke from the furnaces was injurious to the health of that town, there has been a very general protest in the Peninsula against the edict, largely upon the ground that it may have the effect of frightening away foreign capital.—*Ironmonger.*

## THE GOLD DEPOSITS OF NOVA SCOTIA.

*E. Gilpin. Trans. Royal Soc. of Canada, 1889.*

Gold is present in two distinct formations:—

(1.) The lower graphite and ferruginous micaceous schists group, and (2.) the lower quartzite group. The former extends 1,300 m., the latter 3,500 m. The veins of ore vary from 0.32 m. to 2 m., and are very numerous at Mount Uniacke, where no fewer than 31 have been discovered; their depth has been estimated as 100—200 m. According to the latest researches their presence is not, as was formerly thought, in any way dependent on that of the neighbouring granite, which appears more recent than that of the gold formations in the vicinity of Morseland, County Harbour Narrows, &c. The granite usually carries no metal of any kind, though copper has been observed by itself near Dalhousie, Queen's County. The gold is usually accompanied by various pyrites, including copper pyrites and arsenical pyrites. At the Dufferin gold mine, on Salmon River, Halifax County, the vein varies from 0.6 to 4 m., and of 400 m. 80 m. have been worked out, yielding 55,483 tons of quartz containing 27,814 oz. of gold. The gold is widely distributed, but only here and there in paying quantities. It is now well established that the gold is always obtained from, and associated with, schists. As regards the depth to which the lodes extend, it seems probable that those rich in gold deteriorate as they descend, and on a vein suddenly ceasing to yield rich ore, one running parallel to it will be found to carry more gold with equal abruptness, but no direct proof is yet forthcoming.

—B. B.

## EXPORTS OF SPANISH HEMATITE IRON ORE.

The *Bilbao Maritimo y Comercial* shows that the exports of Spanish hematite iron ore from that port alone last year were nearly up to the heaviest on record. The only year in which they were exceeded was 1887, at which

period the price of the mineral ruled very much lower than in 1889:—

	Tonn.
1878 .....	1,221,730

1889 .....	3,851,635

—Ironmonger.

### OUR FOREIGN TRADE IN 1889.

Sir Rawson W. Rawson, chairman of the Commercial Committee of the Imperial Federation League, has compiled the following particulars concerning our foreign trade in 1889:—

#### YEAR 1889 COMPARED WITH THE YEAR 1888.

##### A.—Imports.

1. Tonnage of vessels entering United Kingdom has increased from—  
27,977,000 to 28,518,000 = 5.0 per cent.
2. Value of imports has increased from—  
386,582,000*l.* to 427,211,000*l.* = 10.5 per cent.
3. Average price per ton has increased from—  
14*l.* 6*s.* to 14*l.* 18*s.* = 4.2 per cent.

##### B.—Exports.

1. Tonnage of vessels clearing from United Kingdom has increased from—  
31,664,000 to 33,049,000 = 4.3 per cent.
2. Value of exports has increased from—  
297,885,000*l.* to 313,031,000*l.* = 5.1 per cent.
3. Average price per ton has remained stationary at 9*l.* 8*s.*

#### READINGS FOR THE YEAR 1889 COMPARED WITH 1888.

1. The character of the year 1889 is one of uniformly moderate increase with the exception of—  
(a.) Price of coal, which has advanced 21.3 per cent.  
(b.) Price of gross exports, which has remained stationary.  
(c.) Tonnage of exports, exclusive of coal, which is almost the same.

2. Imports have increased in volume 5.0 per cent.

“ “ “ value 10.5 “  
“ “ “ price 4.2 “

3. Total exports have increased in volume 4.3 per cent.

“ “ “ value 5.1 “  
“ “ “ remained in price stationary.

4. Tonnage employed in the export of coal formed 58.4 per cent. of the total tonnage cleared; in 1888 it formed 56.8 per cent. The quantity of coal exported showed an increase of 7.4 per cent. compared with an increase of 10.2 per cent. in 1888. The increase in the first five months was sixfold that in the last seven. There has thus been a check to the previous rapid increase of this exportation.

5. The quantity of bunker coal showed an increase of 8.6 per cent. This affords some (a minimum) measure of the increase in the tonnage of steam—compared with sailing—vessels which cleared in 1889, as the increase of total tonnage clearing was only one-half—viz., 4.3 per cent.

6. The increased price of coal advanced 21.3 per cent., but this affected the total value of exports by less than 1 per cent.

7. The tonnage clearing with exports, exclusive of coal, increased only 0.3 per cent., but the value of exports increased 4.1 per cent., which was caused by an advance in price, which figures as 3.9 per cent.

8. The value of United Kingdom produce exported increased 6.5 per cent.; that of foreign and colonial merchandise, 1.4 per cent.

#### AS REGARDS MONTHLY FLUCTUATIONS.

The first four months and the last three have been the periods of greatest activity in the export trade both of British and foreign and colonial merchandise.

#### EXPORTS IN 1889 COMPARED WITH 1888.

	British.	Foreign and Colonial.
	Per Cent.	Per Cent.
January to April .....	Increase, 8.4	Increase, 16.8
May to September .....	“ 2.0	Decrease, 16.9
October to December ...	“ 11.1	Increase, 11.6

#### AS REGARDS DESCRIPTION OF MERCHANDISE.

1. Of the ten groups of imports, as classified by the Board of Trade, all have increased except metals. This is shown in the following table, in which the groups are arranged according to the proportionate importance of each:—

##### Imports in 1889.

	Proportion of Total Value.	Increase in Value of each Group.
	Per Cent.	Per Cent.
1. Articles of food and drink .....	37.7	7.9
2. Raw materials for textiles .....	21.4	13.4
3. Manufactured articles .....	15.3	11.2
4. Raw materials, other than above .....	10.2	19.0
5. Metals .....	5.0	Decrease, 5.0
6. Miscellaneous articles .....	3.4	Increase, 4.8
7. Animals, living, for food .....	2.4	31.0
8. Chemicals .....	2.0	6.4
9. Oils .....	1.7	10.7
10. Tobacco .....	0.9	40.8
Total .....	100.0	10.5

2. Of the ten groups of exports all have increased, as shown in a similar manner in the following table:—

##### Exports in 1889.

	Proportion of Total Value.	Increase in Value of each Group.
	Per Cent.	Per Cent.
Produce of United Kingdom:—		
1. Yarns and textile fabrics .....	35.2	1.2
2. Metals and manufactures thereof, except machinery, &c. ....	13.1	10.2
3. Miscellaneous manufactures .....	10.5	6.6
4. Raw materials (chiefly coal) .....	5.5	24.1
5. Machinery and millwork .....	5.0	17.9
6. Apparel, &c. ....	3.7	2.0
7. Articles of food and drink .....	3.4	4.7
8. Chemicals .....	2.5	6.7
9. Animals, living .....	0.4	12.6
10. Foreign and Colonial .....		
Total .....	100.0	5.1

## METALS IN 1889.

(From W. T. Sargant and Son's Annual Circular.)

Coke and carb. works .....	3,000	2,500
	132,000	122,800

**Monthly Patent List.**

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

**1.—GENERAL PLANT, APPARATUS, AND MACHINERY.**

**APPLICATIONS.**

1889.

20,530. R. Tervet and G. Reid. Filter presses. December 21.

20,548. J. R. Watson. Improved retort and filter stand. December 21.

20,569. G. H. Bolton. Improvement in or appertaining to caustic soda drum lids and the like, and to the attachment of such lids, metallic labels, or the like to caustic soda drums, or other sheet metal structures. December 21.

20,739. A. H. Hobson. Dessicating apparatus. December 24.

20,784. R. A. Robertson and W. J. Murreles. Apparatus for evaporating, concentrating, and distilling liquids. December 27.

20,792. A. Lusuardi and A. Faleo. Pressure and vacuum gauges. December 27.

20,925. J. E. Bedford. Apparatus for exposing liquids to the action of gases. December 31.

20,954. J. Wright. Apparatus for distilling, evaporating, or concentrating liquids or solutions and the like, and for condensing exhaust steam. December 31.

1890.

206. J. F. H. Gronwald and E. H. C. Oehlmann. Sterilising apparatus. Complete Specification. January 6.

210. T. Thorp. A frictionless metallic gas-pressure gauge. January 6.

266. A. Brock and H. A. Romero. Improved air pump. Complete Specification. January 7.

341. C. Nield. Improved water filter. January 8.

386. A. Simpson. Improvements in salt pans. January 9.

398. W. Wild. Apparatus for the evaporation of liquids. January 9.

474. C. Blagburn. Apparatus for treating liquids and solids with gases. January 10.

510. T. E. Wilson. The concentration of liquids by evaporation. January 11.

## COMPLETE SPECIFICATIONS ACCEPTED.\*

1889.

499. F. H. Danehell. Means or apparatus for separating solid matters from liquids. December 25.

1078. H. Green and A. Green. Purifying water and removing crustation from steam boilers. January 8.

1345. B. Nicholson and T. Palmer. Rotating vessels for use in tanning, washing, emulsifying, churning, &c.; applicable for treating materials in vacuo or under fluid pressure. December 31.

1424. C. F. H. Hayes. Apparatus for compressing air, gases, or other elastic fluids. January 8.

2603. W. Beaumont. Centrifugal pumps. January 8.

2806. A. Waldbauer. Centrifugal apparatus for continuously washing, dyeing, impregnating, &c. various materials and fabrics. December 31.

2837. Clement, Baron of Bechtolsheim. Centrifugal separators. December 25.

3016. Sir B. Samuelson, Bart.—From G. Maffei. Separating liquids of two different densities. December 31.

3736. M. J. E. Vasscl. Apparatus for filtering liquids, or for preparing extracts from substances. January 15.

4340. H. Halpin and P. W. Willans. Means and apparatus for condensing steam. January 15.

5197. J. C. Mewburn.—From La Société des Generateurs à Vaporisation Instantanée (Système Serpollet). Apparatus for generating steam. December 31.

12,973. The Water Softening Company, Limited, E. Easton and H. Carrod. Apparatus for softening and filtering water or other liquids under pressure. January 15.

13,761. J. Wach. Improvements in thermostats and apparatus operated by differences in the thermal expansion of metals. December 25.

16,763. J. Popper. Condensing vapours and cooling gases or liquids. December 31.

## II.—FUEL, GAS, AND LIGHT.

## APPLICATIONS.

1889.

20,174. J. J. Robins and W. Shakespeare. An improved self sealing door for gas retorts and other purposes. December 16.

20,243. D. McDonald. Improved coal bricks. December 17.

20,255. T. S. Brown and A. W. Brown. Increasing the illuminating power of gas, called the "Aeme gas-saver." December 17.

20,368. W. L. Wise.—From L. Semet, Belgium. Improvements in coke ovens. December 18.

20,370. J. Morley. Improvements in preparing material for and in compounding firelighters, and in means therefor. December 18.

20,432. T. H. Gray and S. S. Bromhead. Improvements in the preparation of coal gas for combustion, and in apparatus for the same. December 19.

20,551. J. West. Improvements in machinery for charging gas retorts. December 21.

20,679. A. Myall.—From J. H. Laneaster, United States. Improvements in smokeless and gasless fuel. December 23.

20,980. H. E. Newton.—From the Fuel, Gas, and Light Improvement Co. Incorp., United States. Improvements in the process of and apparatus for manufacturing gas. December 31.

20,981. H. E. Newton.—From the Fuel, Gas, and Light Improvement Co. Incorp. Improvements in apparatus for the manufacture of gas. December 31.

1890.

27. A. M. Clark.—From D. Dull, United States. Improvements in distilling heavy crude petroleum oils. January 1.

44. S. J. Bull. Improvements in scoops for charging gas retorts. January 1.

67. T. Parker. Improvements in the distillation of coal, shale and the like, the invention comprising the production of a special description of coke. January 2.

260. J. Stears. Improvement in preventing deposit of carbonaceous matter in ascension pipes used in gas-making. January 7.

343. W. T. Cotton and E. F. B. Crowther. Improvements in making gas from coal by vertical fireclay or metal retorts, which are tapered internally, and fitted with slide valves which are encased in iron or steel boxes underneath the retorts to empty them when required, and circular pans at the outlet containing water, to make the valve-boxes and retorts air-tight. January 8.

344. G. Craig. Improvements in the coking of coal and in the ovens employed therefor. January 8.

373. G. H. Hunt. An improved compound of materials for economising smoke in furnaces and other fireplaces. January 9.

502. J. K. Thompson. Improvements in blocks of briquettes made from coal or other material. January 11.

552. W. C. Sellar. Improvements in gas producers. January 11.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

50. C. F. Claus. Production of mixtures of hydrogen and carbonic oxide; and obtaining hydrogen, carbonic oxide, or carbonic acid severally, and certain by-products. December 25.

1806. C. H. Mowll. Improved composition of artificial or block fuel. December 25.

1955. W. Wells. Burner for converting oils or spirits into vapour or gas to obtain light or heat. December 25.

2796. H. Darby. Apparatus for generating and burning gases from hydrocarbon oil and water. December 25.

3394. G. R. Hislop. Apparatus for charging gas producers and gas or shale oil retort furnaces with hot residual coke. December 31.

3936. J. Channon. Firelighters. January 15.

4168. W. Pariby. Instrument for clearing gas-retort ascension pipes. January 15.

6090. F. H. Briggs. Apparatus for the manufacture of water-gas. December 25.

7539. J. T. Ellis. Improvements in apparatus for condensing smoke in the furnaces of steam and other boilers. December 25.

12,460. S. Elliott. Improved method of and apparatus for the treatment of smoke. January 15.

14,287. M. A. Morse. Improvements relating to the manufacture of gas, and to apparatus therefor. December 11.

16,486. A. Coze. Improvements in gas retorts and in apparatus connected therewith. December 25.

18,502. E. Fales. Improvements in and relating to the method of and apparatus for burning coal and other fuel in furnaces. December 25.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

#### APPLICATIONS.

1890.

67. T. Parker. *See* Class II.

178. P. Richin. Process for separating phenol and the cresols from cresote, and for obtaining the said substances in a pure condition. January 4.

### IV.—COLOURING MATTERS AND DYES.

#### APPLICATIONS.

1889.

20,219. J. Imray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, France. Improved manufacture of azoxyaniline and of colouring matters derived therefrom. December 16.

20,292. J. Imray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis. The production of a substituted meta-diamine and of colouring matter derived therefrom. December 17.

20,497. O. Imray.—From The Farbwerke vorm. Meister, Lucius, und Brüning, Germany. Manufacture of non-plumbiferous lakes. December 20.

20,668. J. Y. Johnson.—From The Badische Aniline und Soda Fabrik, Germany. Improvements in and relating to the manufacture of colouring matters suitable for dyeing and printing. December 23.

20,678. O. Imray.—From The Farbwerke vorm. Meister, Lucius, und Brüning. Production of compounds of the diphenylmethane group and the rosaniline series. December 23.

20,924. J. E. Bedford. Improvements in the treatment of logwood and logwood extract for dyeing and printing. December 31.

1890.

39. R. J. Friswell. Improvements in the manufacture of raw materials for dyestuffs. January 1.

134. R. J. Friswell and A. G. Green. Improvements in the production of azo-colouring matters. January 3.

569. Kern and Sandoz. Improvements in the manufacture of blue colouring matter. January 11.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1888.

18,709. E. Edwards.—From Standaert Brothers. A new or improved blue dye. December 25.

1889.

1771. B. Willeox.—From The Farbenfabriken vorm. F. Bayer and Co.—Manufacture of para-amido-phenol ethers. January 8.

3333. T. R. Shillito.—From J. R. Geigy and Co. Production of triphenylmethane colours dyeing with the aid of mordants. December 31.

3529. B. Willeox.—From The Farbenfabriken vorm. F. Bayer and Co. Production of indulines or induline-like dyestuffs. January 8.

4825. J. Imray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, A.F. Poirrier and D. A. Rosenstiehl. Manufacture of azo-colouring matters. December 25.

5032. J. Imray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis. Manufacture of colouring matters giving grey, brown, and analogous tints. December 25.

11,795. H. H. Leigh.—From R. G. Williams, United States. Colouring matters. December 25.

14,294. H. H. Leigh.—From R. G. Williams, United States. Improvements in dye colours. December 25.

18,901. C. Dreyfus. Manufacture and production of colouring matters for dyeing and printing. January 8.

### V.—TEXTILES, COTTON, WOOL, SILK, Etc.

#### APPLICATIONS.

1889.

20,314. H. A. Lowe. Improvements in the treatment of or finishing of manufactured or partly manufactured materials from cotton or similar fibres or other substance containing cellulose. December 17.

20,665. C. Baswitz. Improvements in the treatment of textiles and similar fabrics by means of ammoniacal oxide of copper, to increase the waterproof and non-combustible character of the fabrics. Complete Specification. December 23.

20,771. R. J. Maclean. An improved method or process of producing mixed coloured silk for obtaining mixed coloured silk fibre or mixed coloured yarn. December 27.

20,936. L. Pinagel. A process and apparatus for freeing wool from grease. Complete Specification. December 31.

1890.

200. J. Walker and W. Brown. Improvements in apparatus for drying or carbonising fabrics composed of animal and vegetable fibres, wool, silk, cotton, flax, rags, or other like fibrous substances. January 6.

#### COMPLETE SPECIFICATION ACCEPTED.

1889.

7715. C. H. Hine and J. H. Noad. Process for waterproofing and preserving textures and other materials. December 31.

### VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

#### APPLICATION.

1890.

142. Improvements relating to the dyeing and waterproofing of textile fabrics. January 3.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

415. A. G. Salamon. Bleaching fibre. January 8.  
 2668. J. Walker and H. Carver. Printing "sanitary" or washable paper-hangings. December 25.  
 2806. A. Waldbauer. See Class I.  
 2984. T. Ingham. Dyeing mixed woven fabrics. December 25.  
 3934. B. Willcox.—From The Farbenfabriken vorm. F. Bayer and Co. Dyeing and printing animal and vegetable fibres. January 15.  
 18,973. L. Weldon. Improvements in machines for dyeing cotton and analogous materials. December 31.

## VII.—ACIDS, ALKALIS, AND SALTS.

## APPLICATIONS.

1889.

20,722. J. C. Fell.—From the American Ammonia Manufacturing Co., United States. A method of and apparatus for obtaining ammonia from atmospheric nitrogen and the hydrogen of decomposed steam. December 24.

20,787. J. Longshaw. The treatment of spent or partially spent acid. December 27.

20,862. W. Smith and C. G. Cresswell. Improvements in the manufacture of nitrate of ammonia and bicarbonate of soda in conjunction therewith. December 28.

20,908. M. B. Mason, S. D. Warren, and F. Warren. Improved method of and apparatus for recovering chemicals from solutions, or when mixed with substances which are volatilisable or destructible by heat, especially adapted for recovering soda from waste liquors of pulp digesters. Complete Specification. December 31.

1890.

283. A. T. Smith, jun. Improvements in the treatment of ammonium chloride, ammonium sulphate, calcium chloride, or calcium sulphate for the obtaining of hydrochloric acid and other valuable products therefrom or thereby. January 7.

381. O. C. Townsend. Improvements in processes and apparatus for the manufacture or preparation of nitrate of potash and other salts. January 9.

393. R. C. Wilson. Improvements in and connected with the evaporation of brine and the manufacture of salt therefrom. January 9.

411. H. J. E. Hemebutte. Improvements in the manufacture of sulphate of copper, and apparatus therefor. January 9.

419. P. R. de Lambilly and E. L. Chabrier. A new or improved process for fixing atmospheric nitrogen, and obtaining ammonia and cyanogen compounds. January 9.

448. F. M. Spence, D. D. Spence, and A. Esilman. Improvements in the manufacture of alum. January 10.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

94. J. Hargreaves, T. Robinson, and J. Hargreaves. See Class IX.

2160. L. Mond. Apparatus for volatilising ammonium chloride. December 25.

2575. L. Mond. Volatilising ammonium chloride, and obtaining ammonia, chlorine, and hydrochloric acid therefrom; also obtaining chlorine from hydrochloric acid. December 25.

2786. E. K. Muspratt and G. Eschellman. Manufacture of chlorates, and of magnesium hydrate for use therein. December 25.

3071. J. S. MacArthur. Obtaining cyanides from residuary liquors of chemical processes. December 25.

3072. J. S. MacArthur. Obtaining cyanides from residuary liquors. December 25.

3407. A. Campbell and W. Boyd. Obtainment of chlorine and sulphate of lime. January 8.

3757. T. B. Saunders. Treating or utilising the spent or residual liquor formed in the process of cleaning iron or steel with hydrochloric acid. January 8.

4037. J. B. Hannay. Process and apparatus for manufacture and transport of liquid chlorine. January 15.

4316. E. Carez. Manufacture of ammonium nitrate. January 8.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

## APPLICATIONS.

1889.

20,176. W. H. Hollinshead and H. Griffiths. Improvements in appliances to be used for printing on, or ornamenting ceramic ware. December 16.

20,233. J. J. Candlish and W. Hyslop. Improvements in the manufacture of glass bottles and other hollow glassware, and in apparatus relating thereto. December 16.

20,234. J. J. Candlish and W. Hall. Improvements in the manufacture of glass bottles and other hollow glassware, and in apparatus relating thereto. December 16.

20,328. D. Webb. Improvements in the "posts" or "pontils" used in the manufacture of articles of "pressed glass." December 18.

20,470. J. Campbell. Improvements in drying kilns. December 20.

20,572. A. Griffiths. Improvements in the manufacture of fire-clay pipes, called "swan-necks." December 21.

20,599. G. Waller. An improved method of producing or making pictorial or decorative earthenware tiles by photographic means. December 23.

20,619. J. G. Sowerby. An improved method of cutting or dividing glass cylinders and other forms or articles of glass ware. December 23.

20,687. S. Washington. Improvements in tanks or furnaces used for melting or founding glass. December 24.

1890.

211. T. T. Liddle. Improvements in or relating to the manufacture of glass bottles. January 6.

342. J. Gimson and Challinor. An improved appliance for supporting china and earthenware cups whilst being fired. January 8.

352. E. Robson. An improved production of porcelain tablets or letters. January 8.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

153. J. B. Adams. Method and apparatus for making solid or hollow articles from molten glass or other plastic material. January 8.

161. T. Willett. Process and apparatus for making plates, &c. in earthenware, china, &c. December 31.

2776. J. Thorne. Manufacture of coloured lenses for signal lamps. December 25.

16,264. W. West. Improvements in the mode and means employed for the manufacture of flower or plant pots or other articles from clay or other semi-plastic material. January 15.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

## APPLICATIONS.

1889.

20,303. C. Smith.—From G. P. V. Neilsen, Denmark. A new or improved artificial asphalt. December 17.

20,848. A. Smith. A manufacture of artificial stone. December 28.

20,914. A. Klapperstuck and A. H. Meyer. Improvements in fireproof ceilings and walls. December 31.

1890.

428. A. Wright. An improved weathered facing brick for building purposes. January 9.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

91. J. Hargreaves, T. Robinson, and J. Hargreaves. Treating lime refuse from alkali works to render it suitable for manufacture of cement, and apparatus therefor. January 8.

116. R. Stone. Manufacture and utilisation of cement and plaster, and appliances therefor. January 15.

1262. A. McLean. Method and means for manufacturing blocks of artificial stone. December 31.

1952. J. C. Merryweather. Improvements in paving. January 15.

2718. A. C. Ponton, B. L. Mosely, and C. Chambers. Preparation of siliceous materials used in the manufacture of artificial stone. December 25.

2780. A. C. Ponton, B. L. Mosely, and C. Chambers. Artificial stone. January 15.

2781. A. C. Ponton, B. L. Mosely, and C. Chambers. Manufacture of artificial stone. January 15.

3354. A. C. Ponton, B. L. Mosely, and C. Chambers. Blocks or bricks of siliceous materials. December 31.

3355. W. Hubbard, B. L. Mosely, and J. S. Fairfax. Wall tiles or linings. December 31.

3357. H. H. Leigh.—From L. H. Clansen. Manufacturing artificial stone. December 31.

3378. C. Güttler. Method and apparatus for forming disintegrated or loose material, such as sugar, clay, cement, &c. into compact bodies. December 31.

4333. G. Batebelor. Drying slurry by waste heat from cement kilns. January 8.

4347. J. Homan. Fireproof structures and bricks for same. January 8.

10,997. J. B. King. Composition or plaster for the treatment of walls and the like. January 8.

17,640. W. P. Thompson.—From C. Kohn, Austria. Manufacture of artificial stone or of articles formed of the same. January 8.

## X.—METALLURGY, MINING, Etc.

## APPLICATIONS.

1889.

16,776A. J. B. Alzugaray. A new or improved universal furnace for the fusion and refining of metals, alloys, dross, &c. by the dry process or otherwise, called "the Baxeres universal furnace." Originally included in No. 16,776, dated October 24, 1889.

20,180. R. F. Neuninger. A new combined smelting and reverberatory furnace and apparatus for catching the dust and condensing the fumes from the furnace. Complete Specification. December 16.

20,181. T. Young. Improvements in treating ores to obtain precious metals, and in apparatus therefor. December 16.

20,210. J. Hobson. Improved means of separating particles of iron or of magnetic oxide of iron from admixture with other substances. December 16.

20,214. S. Pearson and J. H. Pratt. Improvements in the manufacture of alloys of aluminium. December 16.

20,223. E. Taussig. Improvements in and relating to casting. December 16.

20,264. A. Gutensohn. An improved method of and process for annealing metal plates and sheets. December 17.

20,313. W. P. Thompson.—From J. Brown, New Zealand. Improvements in washing out or separating gold dust and other heavy metallic particles from impurities, and in apparatus therefor. December 17.

20,380. J. E. Bott. Improvements in the manufacture of compound armour plates and similar articles. December 18.

20,395. T. Brady, T. C. Powers, M. J. Quinn, and A. J. Maher. Improvements in apparatus for casting ingots. December 18.

20,586. J. H. Darby. Improvements in the manufacture of steel or ingot iron. December 21.

20,587. J. Lysaght. Improvements in galvanising apparatus. December 21.

20,677. W. L. Wise.—From J. B. Walker, United States. Improvements in apparatus for treating finely-divided metalliferous material for the purposes of separation and amalgamation. December 23.

20,860. B. H. Thwaite. Improved open-hearth steel and high-temperature furnace. December 30.

1890.

70. I. Bang and A. Ruffin. Improved process for separating tin from other metals, more particularly applicable for the treatment of tin plate scrap and old tinned cases. January 2.

128. I. Bang and A. Ruffin. Improvements in the production of tin plates, and in apparatus for that purpose. January 3.

190. B. Talbot, jun., and J. Hardecastle. Improvements in the production of ingots or masses of steel and alloys thereof. January 4.

191. B. Talbot, jun., and J. Hardecastle. Improvements in or applicable to the manufacture of tubular, hollow, or dished ingots, and other articles of steel and alloys thereof. January 4.

213. J. Mackintire. Improvements in the manufacture of steel and iron. January 6.

237. R. Brown and G. H. Irvine. Improvements in the wet method of extracting gold from finely-divided auriferous quartz ores or other auriferous material, and in apparatus therefor. Complete Specification. January 6.

316. J. E. Chaster. Improvements in the extraction of metals from ore. January 8.

537. W. P. Thompson.—From H. Kromberg, Prussia. Improvements in tuyeres for cupola, &c. and other blast furnaces (hoehofenform). January 11.

560. T. Twynam. Improvements in the manufacture of copper. January 11.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1888.

14,400. H. Hutchinson. Treatment of complex gold and silver-bearing ores, &c., and recovery of metals therefrom. January 15.

14,445. P. Marino. See Class XI.

1889.

15,066. R. Hannan.—From J. J. C. Smith (New Jersey). A process for casting in aluminium bronze dies, to be used for the purpose of stamping metals or other substances for which dies are used. January 8.

19,145. F. A. Herbertz. Smelting furnaces. January 8.

19,621. D. Dennes and T. K. Rose. Improved process or means for extracting precious metals from their ores. January 15.

### XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

#### APPLICATIONS.

1889.

19,861A. C. H. Logan. Improvements in plates for secondary voltaic batteries. Complete Specification. December 10. Originally included in No. 19,861 of that date.

20,217. F. Marx. Process of manufacturing metallic electrodes. Complete Specification. December 16.

20,516. G. Philippart. Improvements in the construction of secondary batteries. December 20.

20,752. F. Marx. Improvements in the manufacture of electrodes for electric batteries. December 24.

20,856. D. G. Fitzgerald and A. H. Hough. Improvements in elements for voltaic batteries. December 28.

20,911. A. E. Woolf. Improved battery plates for storage batteries. Complete Specification. December 31.

1890.

29. S. U. Dardier. Improvements in the electrical coating of metals on non-metallic substances. January 1.

232. J. Hopkinson, E. Hopkinson, and G. A. Grindle. Improvements in electric motors and dynamo-electric machines. January 6.

249. W. F. King. Improvements in dynamo-electric machines. January 7.

302. H. H. Lake.—From P. H. Alexander, United States. Improvements in secondary or storage batteries, and in the manufacture of plates therefor. Complete Specification. January 7.

303. H. H. Lake.—From P. H. Alexander. Improvements relating to secondary batteries. January 7.

350. L. Epstein. Improvements in the formation of electrodes for use in primary and secondary electric batteries. January 8.

488. M. Sappey. Improvements in and connected with primary batteries. January 10.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1888.

14,445. P. Marino. The extraction and electro-deposition of aluminium and aluminium alloys. December 18.

1889.

1420. F. King. Secondary batteries. December 25.

2331. W. H. Dowland and W. Mills. Apparatus for economically effecting the double decomposition of certain substances by the aid of electricity. January 15.

3502. A. G. Greenway, B. F. Babcock, and B. Radcliffe. Improvements in processes for manufacturing iron, wherein the iron is subjected to an electric treatment. January 15.

18,365. J. B. Entz and W. A. Phillips. Plates for primary and secondary batteries. December 25.

18,953. Macanlay-Cruikshank.—From Johnson and Smith. An improved electrode for secondary batteries or accumulators. December 31.

18,966. O. A. Enholm. Primary or galvanic batteries. December 31.

18,989. W. F. Smith. Secondary or storage batteries. December 31.

19,861. C. H. Logan. Secondary batteries. January 15.

19,861A. C. H. Logan. Plates for secondary voltaic batteries. January 15.

19,883. J. K. Pumpelly and F. D. Thomason. Electrical secondary batteries. January 15.

19,899. W. P. Thompson.—From M. W. Parish, United States. Improvements in or relating to electric batteries. January 15.

### XII.—FATS, OILS, AND SOAP MANUFACTURE.

#### APPLICATIONS.

1889.

20,237. W. Rödiger. Improvements in and relating to the manufacture of soap. Complete Specification. December 16.

1890.

540. J. L. Wade. An improved non-freezing and lubricating oil. January 11.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1888.

18,857. H. H. Lake.—From La Société Anonyme des Parfums Naturels de Cannes. Purification of fatty substances and apparatus therefor. December 31. (Advertised in official Journal by error as accepted December 4, 1889.)

1889.

5353. W. G. Smith. Manufacture of soap. December 31.

9410. A. H. Parker. Improved cleansing, scouring, and bleaching compound for wool and other fabrics, also applicable to cleansing purposes generally. December 31.

18,592. J. Y. Johnson.—From L. Genevois, Italy. Improvements in the treatment or preparation for consumption of soft soaps and other like materials. December 25.

19,158. P. Heinz. A new or improved method for sweetening margarine butter and other oils and fats. December 31.

19,948. W. Grills and M. Schroeder. Improved process for the extraction of fats and oils from substances containing the same by means of sulphurous acid. January 15.

### XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

#### APPLICATIONS.

1889.

20,289. J. Y. Johnson.—From N. C. Mitchell, United States. Improvements in and apparatus for the treatment of waste rubber goods to recover the rubber therefrom, and the production of a new product by such treatment. December 17.

20,707. R. Mullard. An improved method of making paints and varnishes, and of the treatment of gums and resins for the same, for preservative, decorative, and artistic purposes; for preserving the plates of iron and steel ships from corrosion, and the bottoms of ships from fouling. December 24.

20,830. C. Huelser.—From G. Calmann, Germany. An improved process and composition for producing printing ink. December 28.

1890.

71. G. Bischof. Improvements in the manufacture of white lead and apparatus for that purpose. January 2.

280. J. Robson. Improvements in the method of protecting iron and steel surfaces from corrosion, and in coatings for the same. January 7.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

13,792. J. J. Carr. Material for making whitewash, colour-wash, and water-colour paints. January 8.

15,826. A. J. Boulton.—From W. Keil, United States. Manufacture of vulcanised plastic compounds. January 15.

18,076. H. H. Lake. From J. B. Tibbits, United States. Manufacture of white lead. January 15.

### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

#### APPLICATIONS.

1889.

20,403. J. Hutchings and W. N. Hutchings. Improvements in the method of and apparatus for extracting the tannin from bark or other materials used for tanning purposes. December 18.

1890.

556. G. Rothel. An improved glue or cement. January 11.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

1345. B. Nicholson and T. Palmer. *See Class I.*

18,503. R. W. Johnson. Improvements in and relating to plastics, more especially designed for imparting to glue a permanent elasticity and adapted to be used for several purposes. December 25.

### XV.—AGRICULTURE AND MANURES.

#### COMPLETE SPECIFICATION ACCEPTED.

1889.

18,918. E. Saxl and H. Saxl. Fertilisers. December 31.

### XVI.—SUGARS, STARCHES, GUMS, Etc.

#### APPLICATIONS.

1889.

20,515. C. Steffen. An improved process for obtaining the entire quantity of crystallisable sugar contained in sugar mass. Complete Specification. December 20.

1890.

357. S. Wöhle, A. C. Irwin, and G. O. Jacob. Improvements in the preparation of dextrine. January 8.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

3378. C. Güttler. *See Class IX.*

4121. F. Demmin. Cleansing or whitening sugar in the centrifugal machine, and apparatus therefor. January 15.

19,728. W. Thompson, J. Myle, and J. B. Alliot. Apparatus for the expression of juice from sugar cane. January 15.

### XVII.—BREWING, WINES, SPIRITS, Etc.

#### APPLICATIONS.

1889.

19,796A. J. Fisher. Improvements in making bread and fermenting liquids. Previously included in No. 19,796, filed December 4, 1889.

20,298. E. Larsen. Utilisation of brewers' or distillers' yeast. December 17.

20,409. C. Gillett and H. Young. The utilisation of brewers' and distillers' grains in the manufacture of a cake or meal as a food for horses, cattle, pigs, and other animals. December 19.

20,434. B. Hoff and J. Frommel. Apparatus for use in rectifying spirits and other matters. December 19.

20,630. L. Haas. Apparatus for collecting for further utilisation the excess of carbonic acid generated during the manufacture of beer. (Date applied for June 27, 1889, being date of application in Switzerland.)

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

3468. B. Hoff. Improvements relating to distillation, and apparatus therefor. December 31.

5564. W. P. Thompson.—From La Société Generale de Maltose. Manufacture of maltose and fermentation of amylaceous matter. December 25.

15,401. A. J. Boulton.—From Otto and Schwerdtfeger, Saxony. Preservation of beer and the like. December 31.

17,523. H. H. Lake.—From J. Barnes, United States. Yeast cakes. January 15.

19,376. J. F. H. Gronwald and E. H. C. Oehlmann. Process for treating beer and making it keep permanently in good condition. January 15.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

## APPLICATIONS.

*A.—Chemistry of Foods.*

1889.

20,182. E. Sonstadt. Improvements in processes and apparatus for the preparation of an extract of tea, and in the utilisation of the by-products. December 16.

20,336. E. Sonstadt. Improvements in processes and apparatus for the preparation of an extract of coffee, and in the utilisation of the by-products. December 18.

20,614. W. Douglas and J. Donald. Improvements in preserving fish, birds, poultry, or other analogous articles of food. Complete Specification. December 23.

1890.

192. J. H. Hooker. A new or improved alimentary liquid. January 4.

*B.—Sanitary Chemistry.*

1890.

16. J. Smillie. Treating water for preventing action on lead. January 1.

149. H. Guthrie. Improvements in treating sewage, and in the construction and arrangement of means therefor. January 4.

206. J. F. H. Gronwald and E. H. C. Oehlmann. See Class I.

309. T. Kay. Improved economical processes in the treatment of sewage. January 7.

472. C. Jones. Improvements in or connected with destructors and other furnaces for treating refuse. January 10.

480. E. Devonshire. Improvements in purifying water. January 10.

*C.—Disinfectants.*

1889.

20,231. A. Artmann and H. W. Kufeke. Improvements in the process of producing disinfectants. December 16.

20,426. A. Muirhead. Improvements in apparatus for the production of ozone. December 19.

## COMPLETE SPECIFICATIONS ACCEPTED.

*A.—Chemistry of Foods.*

1889.

5052. F. McIntyre. Improvements in the making of butter for the purpose of preserving the same. January 15.

14,670. A. A. Freeman. Preservation of shell fish. January 15.

*B.—Sanitary Chemistry.*

1889.

15,190. H. Rohrbeck. Method and apparatus for disinfecting by means of saturated steam of a high temperature. December 25.

## XIX.—PAPER, PASTEBOARD, ETC.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

16,342. D. C. Simpson. A new or improved composition for treating paper and similar material to render writings or other markings indelible thereon. December 25.

18,090. I. Appletree. A new composition to be used as a substitute for ivory and for other purposes. December 25.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

## APPLICATION.

1889.

20,392. J. A. Kendall. Improvements in the manufacture of hypophosphites. December 18.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

3745. A. Domeier. Fixing perfumes. January 15.

10,280. H. H. Lake.—From la Société Anonyme des Parfums Naturels de Cannes. Process of recovering volatile solvents retained in substances treated therewith. January 8.

## XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

## APPLICATIONS.

1889.

20,526. O. Levens. Improvements in the production by photography of lined images in the preparation of surfaces to be etched. December 20.

20,662. W. H. Caldwell. Improvements in sensitising and developing chloride of silver for photographic purposes. December 23.

1890.

401. T. H. Redwood. Improvements in means or apparatus for producing a flash light, more especially applicable to photography. January 9.

547. J. J. E. Mayall. A new or improved manner of colouring photographic impressions with oil colours. January 11.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

2623. J. Leisk. Flash lamp for the rapid combustion of magnesium powder for photographic purposes. January 8.

2723. F. W. Hart. Apparatus for controlling the exposure of sensitive plates when using flash lamps. January 15.

## XXII.—EXPLOSIVES, MATCHES, ETC.

## APPLICATIONS.

1889.

20,286. E. W. Anderson. Apparatus for cutting into lengths and delivering smokeless explosive or other plastic material which has been moulded through a die. December 17.

20,514. E. Davies. Improvements connected with explosive and non-explosive projectiles, and in an explosive compound to be used with the explosive projectiles. December 20.

## COMPLETE SPECIFICATION ACCEPTED.

1889.

1988. A. V. Newton.—From A. Nobel. Preparing explosive compounds for use. January 8.

## XXIII.—ANALYTICAL CHEMISTRY.

## APPLICATIONS.

1889.

20,755. M. Gehre. New or improved process and apparatus for determining the amount of water contained in steam. December 24.

20,859. I. K. Lindström. An improved method of and apparatus for determining the quantity of fat in milk. Complete Specification. December 28.

## Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 2.—VOL. IX.]

FEBRUARY 28, 1890.

Non-Members 30/- per annum; Members  
21/- per Set of extra or back numbers;  
Single Copies (Members only) 2 6.

## The Society of Chemical Industry.

*Past Presidents:*

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond	1888—1889.

## COUNCIL FOR YEAR ENDING JULY, 1890.

*President:* Sir Lowthian Bell, Bart., F.R.S.*Vice-Presidents:*

R. Forbes Carpenter.	S. H. Johnson.
Prof. F. Clowes, D.Sc.	Ludwig Mond.
Sir J. Neilson Cuthbertson.	Dr. Hugo Muller, F.R.S.
Prof. James Dewar, F.R.S.	Dr. W. H. Perkin, F.R.S.
Jas. Duncan.	Dr. Edw. Schunck, F.R.S.
Dr. John Evans, F.R.S.	Prof. W. A. Tilden, F.R.S.

*Ordinary Members of Council:*

L. Archbutt.	B. E. R. Newlands.
S. B. Boulton.	Jno. Pattinson.
Jno. Brock.	Jno. Spiller.
Jno. Calderwood.	E. C. C. Stanford.
Alexander M. Chance.	J. C. Stevenson, M.P.
A. E. Fletcher.	A. Norman Tate.

With the Chairmen and Secretaries of Sections.

*Honorary Treasurer:*

E. Rider Cook, East London Soapworks, Bow, E.

*Honorary Foreign Secretary:*

Dr. Ferdinand Hurter.

*General Secretary:* Charles G. Cresswell.*Offices:*

Palace Chambers, 9, Bridge Street, Westminster, S.W.

## THE JOURNAL.

*Publication Committee:**The President.*

Sir F. A. Abel, F.R.S.	Prof. A. K. Huntington.
A. H. Allen.	F. Hurter, Ph.D.
G. H. Bailey, D.Sc., Ph.D.	Ivan Levinstein.
Joseph Bernays, M.I.C.E.	Prof. R. Meldola, F.R.S.
H. Brunner.	Ludwig Mond.
W. Lant Carpenter.	E. K. Muspratt.
Prof. Frank Clowes, D.Sc.	B. E. R. Newlands.
W. Y. Dent.	C. O'Sullivan, F.R.S.
Prof. Jas. Dewar, F.R.S.	John Pattinson.
John Heron.	W. H. Perkin, Ph.D., F.R.S.
D. B. Hewitt, M.D.	Sir H. E. Roscoe, M.P., F.R.S.
David Howard.	John Spiller.
Prof. J. J. Hummel.	A. Norman Tate.
	Thomas Tyrer.

## NOTICES.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. FYRE AND SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

#### LIST OF MEMBERS ELECTED, 21st FEBRUARY, 1890.

Adler, Dr. L. N., 197, Pearl Street, New York, U.S.A., chemical manufacturer.

Bealey, Adam C., Manor House, Bury, Lancashire, bleacher and alkali manufacturer.

Brown, S. B., Radcliffe Printing Co., Lim., Radcliffe, Lancashire, printworks manager.

Chaplin, Jas. C., 10, Earl's Court Square, South Kensington, S.W., barrister.

Crossley, L., 7, Pelham Grove, Sefton Park, Liverpool, chemical student.

Cunningham, Calvert G., Alkaline Reduction Syndicate, Hebburn-on-Tyne, assistant manager.

Dodd, Arthur J., River View, Belvedere, Kent, oil refiner.

Field, Chas. H., The Nottingham Brewery, Nottingham, analyst.

Gemmell, Ross, Radcliffe Printing Co., Lim., Radcliffe, Lancashire.

Grabfield, Dr. J. P., 1915, Indiana Avenue, Chicago, Ill., U.S.A., chemist.

Gray, Wm., jun., Southfield, Hessle, Hull, oil refiner.

Gregory, W. J., 76, St. Thomas Street, Weymouth, Dorset, chemist.

Hodges, H. B., c/o Union Pacific R. R., Omaha, Neb., U.S.A., chemist.

Jackman, E. J., 689, Commercial Road, London, E., clerk in chemical works.

Masson, G. H., Government Laboratory, Port of Spain, Trinidad, analytical chemist.

Orsman, W. J., Roburite Explosive Co., Gathurst, near Wigan, chemist.

Proctor, Miss Anne J., Free Library, Widnes, librarian.

Redgate, J. G., Traffic Street, Nottingham, aerated water manufacturer.

Redmayne, R. Norman, 26, Grey Street, Newcastle-on-Tyne, chemical manufacturer.

Sheppee, Lieut.-Col. F. F., Birtley House, Chester-le-Street, co. Durham, colliery proprietor.

Simonds, Dr. Francis M., 147, East 34th Street, New York, U.S.A., assayer.

Simpson, C. H., Moor Top House, Ackworth, Pontefract, soap maker.

Sindall, Robt. W., 40, Station Street, Sittingbourne, Kent, paper mills chemist.

Smith, H. Wood, 51, Arcade Chambers, St. Mary's Gate, Manchester, chemist.

Towns, Wm., Irwell Lane, Runcorn, Cheshire, alkali works manager.

Townsend, C. W., Crawford Street, Port Dundas, Glasgow, chemist.

Wade, Jas. L., 30, West Kensington Gardens, London, W., chemical manufacturer.

Whelan, E. J., Star Chemical Works, Wandsworth Bridge Road, Fulham, S.W., manufacturing chemist.

Wilson, Jno. A., South 20th and Mary Streets, Pittsburgh, Pa., U.S.A., glass manufacturer.

Young, Wm., Priorsford, Peebles, N.B., chemical engineer.

#### CHANGES OF ADDRESS.

### SESSION 1889-90.

1890.

March 3rd:—

Dr. H. Schlichter. "Analysis of Textile Fibres and Fabrics."  
Dr. L. T. Thorne. "A Review of the Methods of producing Oxygen commercially."

March 31st (instead of April 7th—Bank Holiday):—

Election of Committee and Officers of Section. Nominations (signed by 10 members) to be sent to the Honorary Secretary on or before Monday, March 17th. No member shall sign more than one paper.

Dr. W. S. Squire. "Note on a Machine for a Continuous Separation of Solids and Liquids."

Mr. H. W. Langbeek. "Wool-Fat, and Processes for obtaining it, with special relation to Wool-Washing."

Mr. A. W. Eastlake. "The Petroleum Industry in Galicia."

April 21st (extra meeting):—

Professor Meldola, F.R.S., and Dr. E. R. Moritz. "Note on the Expansion of Ammoniacal Compounds from Sulphuric Acid used in Kjeldahl determinations."

Professor Dewar, F.R.S., and Mr. Boverton Redwood. "A Process for the Conversion of Heavy Mineral Oils into Lighter Hydrocarbons suitable for illuminating and other purposes."

May 5th:—Mr. Wm. Webster. "The Electrical Treatment of Sewage."

June 2nd:—Dr. W. S. Squire. "The Artificial Production of Cold theoretically and practically considered."

July:—Annual General Meeting in Nottingham.

Meeting held Monday, 3rd February, 1890.

MR. DAVID HOWARD IN THE CHAIR.

## NOTES ON COMMERCIAL CRESYLIC ACID AND ALLIED PRODUCTS.

BY ALFRED H. ALLEN.

IN conjunction with Mr. W. W. Staveley I have been for some time past experimenting with a view of learning more than has been placed on record respecting the metallic compounds or derivatives of the phenols and allied bodies. It had been our intention to place our results before you this evening, but unfortunately our work has met with repeated and unexpected interruptions, and unforeseen circumstances compel a postponement of our paper. Under these circumstances, and with the permission of the Chairman, I propose to bring before you some notes on certain classes of commercial phenols as now manufactured, which notes may really be regarded as an introduction to the postponed paper.

It is well known that carbolic acid and other phenols are manufactured by treating the fraction of coal tar known as "creosote oil" with caustic soda, separating the insoluble hydrocarbons, and then decomposing the phenolate of soda by means of an acid. Sulphuric acid is the acid most generally employed for this purpose, though hydrochloric and sulphurous acids have also been used. Decomposition of the phenolate of soda by carbonic acid, a reaction

associated with the names of Cliff and Hardman, is now practised in one and probably in several works. West-Knights and Gall have patented (No. 5824, 1887) the extraction of carbolic acid from creosote oil by a mixture of sulphate of sodium and lime, whereby sulphate of calcium and carbolate of sodium are obtained. The liquid is separated from the precipitate of calcium sulphate and the carbolate of sodium treated with sulphuric acid, whereby sulphate of sodium is reproduced and the phenols are liberated. Here the inventors seem to have missed an opportunity, for by employing carbonic acid instead of sulphuric, carbonate of sodium is obtained, and this reaction forms the foundation of Mr. W. W. Staveley's ingenious process of alkali manufacture (Patent No. 17,657, 1887), described in a paper read by him before the Liverpool Section of this Society (Journal, VII., 807). I believe this process would be found very suitable for dealing with waste forms of sulphate of sodium, whether solid or in solution, as the plant is comparatively simple and inexpensive, and the reactions are said to be very complete.

The carbolic acid required for decomposing the soda compounds of the phenols is usually obtained by the combustion of coke containing as little sulphur as possible. But in a patent obtained by Mr. R. Angus and myself (No. 11,689, 1887), we described the use of blast-furnace gases to precipitate the phenoloid constituents of blast-furnace tar from their solutions in alkalis. This process is now carried out on a large scale at the Lurgar Iron Works by the same company that own the Gartsherrie Works.

The crude blast-furnace tar is first distilled, whereby it is separated into pitch and creosote oil, and only trifling quantities of more volatile products. The creosote oil is quite different from gas works creosote, being free from naphthalene and anthracene and lighter than water. It contains from 20 to 30 per cent. of phenoloid bodies removable by alkali, and the extraction of these renders the residual hydrocarbons far more suitable for use with the Lueigen and similar lights, though the high market price obtainable at present for crude creosote oil does not afford much encouragement for the extraction of the phenols. The process employed at Lurgar consists in treating the creosote oil with caustic soda solution of sp. gr. 1.11 to 1.15 in quantity insufficient to remove the whole of the phenoloid bodies present. By operating in this way the higher homologues and oxy-phenols chiefly remain with the insoluble hydrocarbons. The alkaline liquid is separated from the oily layer containing the hydrocarbons, and the excess of phenols, and is decomposed by passing through it blast-furnace gases, whereby the phenols are liberated and a solution of carbonate of sodium obtained. This solution, without either concentration or dilution, is causticised by means of lime, when it is ready for treating another quantity of creosote oil, and thus no further alkali is required, except that requisite to supply actual waste. The phenols thus obtained constitute what the patentees have called crude "neosote," a name suggested by its similarity in composition to wood creosote, but which signifies "new preserver." As originally made, the neosote contained a larger proportion of the oxy-phenols characteristic of wood-tar creosote than is at present the case. In some cases the neosote has been purified by partial resolution in alkali, which removes phenoloids of acid character and high boiling point, which properties give them a special value for certain applications. Redistillation is also sometimes practised, as is treatment with steam or air, which removes a notable quantity of sulphur compounds. When newly manufactured, neosote has the appearance of sherry, but darkens on keeping and exposure to light to that of mahogany. When freshly distilled it is perfectly colourless and scarcely distinguishable from the similar fractions of the phenols from gas tar.

The chemistry of the phenols from blast-furnace tar has been investigated by Professor Watson Smith. On treating 14 gallons of blast-furnace creosote oil (sp. gr. 1.088) with caustic soda of 1.07 sp. gr., and decomposing the alkaline solution with sulphuric acid, he obtained two gallons of phenoloids of 1.07 sp. gr. On fractionally distilling this

he obtained 1.33 per cent. of phenol, against a yield of 65 per cent. from Lancashire gas tars. The fraction which would contain the cresols amounted to only  $4\frac{1}{2}$  per cent. of the total phenoloids. The large fraction (19.4 per cent.) distilling between 210 and 230°, Mr. Smith considered probably consisted mainly of phlorol (mixture of the xlenols) with guaiacol and creosol. The results show that a close similarity exists between the phenoloids of blast-furnace creosote and those contained in wood tar. A large proportion of the creosote examined by Watson Smith distilled above 230°, and the portion distilling above 360° gave, on treatment with soda and exposure to air, unstable colouring matters which are probably allied to the eupitomic acid obtained from wood tar.

It is probable that the extraction of the phenoloids from the sample examined by Mr. Smith was not complete. By repeatedly treating a sample of blast-furnace creosote oil of 1.956 sp. gr. with strong caustic soda (sp. gr. 1.21) I extracted 34 per cent. by measure of crude phenoloids having a density of 1.0355. On distillation these gave very little over below 200°, and 59.5 per cent. below 250°, the largest fraction distilling between 220 and 230°.

As already stated, the blast-furnace phenols now manufactured at Lugar differ considerably from those formerly extracted, as is evident by the figures in the table at the top of the next column obtained by the fractional distillation of a sample of commercial neosote with a Glyusky's fractionator.

It will be observed that 27.8 per cent. passed over between 195° and 200°, and an additional 19.8 per cent. between 200 and 205°. The regular decrease in the specific gravity of the fractions is interesting. The original sample gave 3.15 per cent. of hydrocarbon as the result of a very careful determination.

	Per Cent. by Measure.	Sp. Gr. of Fraction.
Below 174° (Water) .....	1.0	.. .. .
From 174° to 190° .....	4.4	.. .. .
From 190° to 195° .....	10.8	1.0435
From 195° to 197½° .....	21.2	1.0450
From 197½° to 200° .....	6.6	1.0390
From 200° to 202½° .....	11.2	1.0340
From 202½° to 205° .....	8.6	1.0290
From 205° to 210° .....	10.9	1.0255
From 210° to 215° .....	7.8	1.0185
From 215° to 220° .....	8.2	1.0125
From 220° to 225° .....	1.0	.. .. .
Total below 225° C. ....	90.7	

Residue (by difference) 9.3 containing 1.05 of hydrocarbon.

The three isomeric cresols are stated by Schulze (Ber. 20, 419) to exist in gas tar approximately in the proportions of 35 per cent. of orthocresol, 40 of metacresol, and 25 per cent. of paracresol. 1:3:5 and 1:2:4 xlenols have been found in the fraction of gas tar phenols boiling between 170° and 210°.

The following table shows the leading physical and chemical distinctions between the three isomeric cresols:—

	Melting Point. °C.	Boiling Point. °C.	Specific Gravity at °C.	Coefficient of Expansion.	Highest Bromo- Derivative.	Highest Nitro- Derivative.
Orthocresol .....	30; 31–31.8	188; 190.8	1.0578	.00072	Br <sub>2</sub> ; m.p. 52°	(NO <sub>2</sub> ) <sub>2</sub> ; m.p. 85.8°
Metacresol .....	4; 3–4	204; 202.8	1.0498	.00078	Br <sub>3</sub> ; m.p. 82°	(NO <sub>2</sub> ) <sub>3</sub>
Paracresol .....	36; 36–37	201.8; 198–199	1.0522	.00086	Br <sub>2</sub> ; m.p. 49°	(NO <sub>2</sub> ) <sub>2</sub> ; m.p. 82.5°

The melting and boiling points recorded by different observers are not in very perfect concordance. The specific gravities and coefficients of expansion are figures by Pinette (Annalen 243, 43), and apparently refer to the liquid cresols, which exhibit, in a marked manner, the phenomenon of superfusion. The "higher bromo-derivative" means the most highly brominated substitution compound which does not react with potassium iodide. Thus, in the case of phenol it would be C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>OH, and not C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>OB.

Metacresol forms a tribromo- and trinitro-derivative, whereas the ortho- and para-isomerides form only di-substitution products.

In fractionally distilling neosote several very marked breaks occur. Thus, with the sample in question, the temperature remained absolutely constant for a considerable time at 197° and again at 204°.

By fractional neutralisation and distillation of the lower boiling portions of neosote, crystals of impure carboic acid may be obtained by immersing the liquid in a freezing mixture and adding a minute crystal of phenol. Orthocresol did not induce a similar solidification. The crystalline needles melted at 26.0°C., and reacted with 5.02 atoms of Br, the liquid drained from the crystals reacting with 4.54 Br. Calvert's No. 2 crystallised carboic acid reacted with 6.04 Br.

The examination of other samples of neosote has given much the same results as the above, and shows that the article consists chiefly of cresols and their homologues. The presence of the higher homologues has some practical interest, for as a consequence neosote is considerably less volatile and soluble in water than is cresylic acid. The following experiments were made exposing known weights

of neosote and Calvert's No. 5 carboic acid side by side in shallow vessels.

Time of Exposure in Days.	Loss by Volatilisation.	
	Neosote.	No. 5 Carboic Acid.
	Per Cent.	Per Cent.
1	0.84	5.45
2	1.95	7.99
3	3.24	9.39
4	4.55	12.11
5	5.25	13.30
7	5.95	14.18
8	6.65	14.43
11	10.57	19.82
14	14.20	25.02
17	16.68	30.07
21	18.02	35.02
24	19.10	38.46

This moderate volatility of neosote may be an advantage or the contrary, according to the circumstances under which it is intended to be employed.

For comparison I may quote the following results obtained by the distillation with fractionating bulbs of a sample of

crude commercial cresylic acid of 1·049 sp. gr. manufactured from gas-tar :—

—	Measure of Distillate.	Specific Gravity of Fraction.
	Per Cent.	
First drop over at 90° C., water..	8·5	.. ..
Below 180° C. ....	2·5	.. ..
From 180° to 190° .....	4·0	.. ..
From 190° to 195° .....	10·5	1·045
From 195° to 200° .....	20·0	1·043
From 200° to 205° .....	10·0	1·037
From 205° to 210° .....	9·5	1·032
From 210° to 215° .....	6·0	.. ..
From 215° to 225° .....	6·6	.. ..
Total below 225° .....	89·5	.. ..

A sample of "once-run" cresylic acid had a specific gravity of 1·038, and gave on distillation with fractionating bulbs the following figures :—

—	Measure of Distillate.	Specific Gravity of Fraction.
	Per Cent.	
First drop over at 95° C., water..	9·5	.. ..
Below 190° .....	1·5	.. ..
From 190° to 195° .....	15·5	.. ..
From 195° to 200° .....	36·0	1·041
From 200° to 205° .....	19·5	1·034
From 205° to 210° .....	11·0	1·029
From 210° to 215° .....	6·0	.. ..
From 215° to 228° .....	6·5	.. ..
Total below 228° .....	96·5	.. ..

Another sample of commercial cresylic acid of sp. gr. 1·041 gave in the same apparatus :—

—	Measure of Distillate.	Specific Gravity of Fraction.
	Per Cent.	
First drop over at 120° C., water.	None	.. ..
Below 180° .....	0·2	.. ..
From 180° to 190° .....	4·6	.. ..
From 190° to 195° .....	56·6	1·046
From 195° to 200° .....	23·0	1·039
From 200° to 205° .....	10·0	1·030
Total below 205° .....	96·4	.. ..

Calvert's "No. 5 carbolic acid" gave the following results when fractionated :—

	Per Cent.
Below 170° .....	6·8 containing 5·5 per cent. of water.
Between 170° and 183° .....	2·0
Between 183° and 186° .....	3·6
Between 186° and 190° .....	46·8 of 1·0541 sp. gr.
Between 190° and 195° .....	28·8 of 1·0430 sp. gr.
Between 195° and 200° .....	7·0 of 1·0370 sp. gr.
Total below 200° .....	95·0

The antiseptic properties of cresylic acid are generally regarded as being fully equal to, if not superior, to those of carbolic acid, and direct experiment has proved this to be true also of the higher homologues, while if the acrid body of high boiling point already referred to be removed, the effect of the higher homologues on the skin is far less caustic than that of carbolic acid.

I must leave a detailed consideration of the metallic compounds or derivatives of the higher phenols to a future occasion, but may say that I have met with great difficulty in preparing them of definite composition. Of the heavy metals, the phenolates of lead and mercury are the most readily prepared.

I may point out that the phenols present one peculiarity which is capable of several interesting applications. I refer to the fact that their calcium salts are readily soluble in water, but decomposable readily and completely by carbonic acid. With the exception of the compound of lime with cane sugar, and the sulphhydrate of calcium, no other calcium salts occur to me of which the same can be said; and in these cases there is not the same precipitation of the acid in a separate and readily available form that occurs with the phenolates.

#### DISCUSSION.

The CHAIRMAN said that the Section had reason to thank Mr. Allen heartily for the fraction of his paper which he had been able to give them. Some halves were greater than some other wholes; and the matter which Mr. Allen had brought before them was deeply interesting as throwing light upon a most important modern development of chemistry. He would call upon Professor Smith to give the meeting the benefit of his special experience in this direction.

Mr. WATSON SMITH had listened with great pleasure to the particulars brought forward by Mr. Allen, and especially to his promise of further details on this interesting subject. He had started the work in this direction himself, and might mention that it was by isolating in as pure a condition as possible a number of the phenoloid constituents of blast-furnace tar, and afterwards passing them over red-hot zinc dust and obtaining the corresponding hydrocarbons, that he had obtained to some extent the clue to the nature of the phenols which gave rise to them. He did not trouble to pass the carbolic acid over, as it was easy to identify that by crystallisation. But he obtained the cresol in the shape of toluene, and some xylenes afterwards, as also pseudocumene and mesitylene, and a quantity of naphthalene derived from the naphthols present. In his first communication on the subject he had said that probably guaiacol and cresol would be present also; but in his later experiments he had found no indications of their existence in this blast-furnace tar. He could not conceive that guaiacol, especially, could be present and not be detected, for it had a peculiarly strong odour—indeed, it was to the presence of guaiacol in wood tar that the extremely powerful smell of that body was due. In the samples of phenols presented by Mr. Allen, the peculiar odour of guaiacol was not perceptible to him, and they thus so far corroborated the observations made upon the fractions isolated by himself. It was probable, therefore, that what they had before them were merely a mixture of the homologues of phenol, with possibly some hydroxyphenols, but none of the methylated derivatives. Mr. Allen had stated that his cresol contained 1 per cent. of water, and had referred to that as being lower than the usual percentage in commercial cresol. No doubt that would be due to its being freshly distilled.

Mr. A. H. ALLEN, interposing, said that the cresol to which he referred was two years old. It was to be observed that it was a product of distillation of blast-furnace tar, whereas ordinary commercial cresol was a by-product of the manufacture of carbolic acid.

Mr. WATSON SMITH, continuing, said it was characteristic of the cresols that they absorbed or contained less water than phenol. In fact, that characteristic was used as a distinctive proof of identity, and a tar distiller would know that his crude carbolic acid was good if water were present in considerable quantity (about 13 per cent.); whereas if

only a small quantity, say 5 or 6 per cent. were present, he would expect to find a considerable proportion of crude cresol. The small percentage of water contained in Mr. Allen's cresol, therefore, went far to show that it was an unmixed product. The reason for this small percentage as compared with phenol was to be found in the fact that, in the case of cresol, hydrates were not formed, whereas in the case of phenol two hydrates are known, and this accounted for the corresponding absorption of water. The discovery of these hydrates had been the result of special study by Mr. Charles Lowe, of Manchester.

### FEODOSSIEFF'S NEW METHOD OF TEMPERING AND HARDENING STEEL FOR CANNON AND PROJECTILES.

BY WATSON SMITH, F.C.S., F.I.C.

Lecturer in Chemical Technology in University College, London.

PROFESSOR W. C. ROBERTS-AUSTEN, in his very able lecture before the British Association at Newcastle-on-Tyne last year, pointed out the confusion at present existing in the use of the words "hardening," "tempering," and "annealing" as applied to steel. He gave the following definitions: "*Hardening*" is the result of rapidly cooling a strongly heated mass of steel; "*Tempering*" that of reheating the hardened steel to a temperature far short of that to which it was raised before hardening—this heating being followed or not being followed by rapid cooling; whilst "*Annealing*" consists in heating the mass to a temperature higher than that used for tempering, and allowing it to cool slowly.

As I shall hereafter show, the method to be described can either be used for hardening steel or may be modified for tempering or annealing. This method has been invented by Captain G. Feodossieff, of the Imperial Russian Navy (this Journal, 1889, 548). Glycerin is the substance or medium used, and it is employed for the tempering or hardening of steel, cast steel or cast iron. It is proposed to vary the specific gravity of the glycerin from 1.08 to 1.26 at 15° C. by the addition of water according to the composition of the steel and the effects desired. The quantity of glycerin is to be from one to six times greater in weight than that of the pieces to be plunged into it, and in accordance with the hardness of the metal its temperature is to be varied from 15 to 200° C., a higher temperature being employed for the tempering of the harder steels, whilst a lower temperature is used for tempering the milder steels.

Additions of various salts to the glycerin baths are recommended to increase their quenching power. Thus, for a *hard temper*:—Manganous sulphate may be added in quantity varying from 1 up to 34 per cent. of the liquid, or from  $\frac{1}{4}$  to 4 per cent. of potassium sulphate. For a "*softer temper*," 1 to 10 per cent. of manganese chloride and 1 to 4 per cent. of potassium chloride may be added.

The principal advantages claimed for these processes are as follows:—

- (1.) The temperature of the aqueous solutions of glycerin may be varied within wide limits, the boiling point of pure glycerin being 290° C. (By a misprint our Journal, 1889, 548, gives 29° instead of 290° C.)
- (2.) Owing to the fact that solutions of glycerin in water dissolve most salts that are soluble in water, the quenching powers of the glycerin may be readily varied by dissolving such salts in the bath to suit the kind of metal to be tempered and the degree of temper required.

It will be observed that in the directions given in the patent, just those are defined which are necessary for the manufacturer or workman, who already possesses a general knowledge of the subject of "hardening" and "tempering." However, since the date of this patent, Captain Feodossieff writes me that he has made new and further improvements,

and has succeeded in tempering heavy projectiles, armour-plate and railway tyres by his glycerin process, and has obtained very satisfactory results. I have now much pleasure in exhibiting some specimens of steel treated by Feodossieff's process. The first is a 4-inch cast-steel ingot which had been made red hot and then immersed in glycerin. An examination of the upper part of it will show that a peculiar shrinkage has taken place, which proves that the metal has not been forged. This ingot, sent me by Captain Feodossieff from St. Petersburg for exhibition with the other specimens at this meeting, was specially sent for the purpose of showing us that the qualities of the metal are derived from the manner of hardening and not from forging.

Specimen No. 2 is a part of the same ingot as No. 1, but which has been forged, raised to a low heat and then plunged into glycerin. After cooling it was bent at an angle of 180°. The tensile strength of this piece of annealed steel is 65 tons, elongation 15 to 18 per cent. The specimen before us was bent cold. Specimen No. 3 is of forged steel, tempered in glycerin. All three pieces now exhibited, Nos. 1, 2, and 3, are fragments of the same 4-inch ingot.

With regard to the specimen 2, which was bent upon itself cold, analysis proved it to have the following composition: carbon, 0.7 per cent.; chromium, 2.2 per cent.; and silicon, 0.15 per cent. Captain Feodossieff has experimented with unforced cast-steel 12-inch projectiles. One of these penetrated 12-inch armour-plate made by Cammell; the head part of the projectile fell at 10,000 feet behind the target. He now makes 12-inch projectiles which penetrate 16-inch armour-plate. Various experiments have proved that Feodossieff's method of hardening produces an intrinsic change in the molecular structure of the metal.

The inventor proposes that experiments should be made now with guns, which are so difficult to forge, but such experiments ought to be made on a large scale in works like those of Lord Armstrong and Co., Limited, at Elswick, or of Sir Joseph Whitworth and Co. I need hardly point out the great importance of this suggestion if it should be found that by such a uniform method of treatment the absolute uniformity of structure of the strongest and toughest kind so much desired in large ordnance will be insured, and that thereby, as one would *a priori* conclude, a great decrease in the cases of the bursting of cannon be the result, or that such cases be reduced to as nearly zero as possible. When one thinks of the operation of forging it is difficult to believe that, even with the best mechanical contrivances, the result, can be absolutely uniform in all parts of so large a piece of metal as that serving for the construction of a large piece of cannon. If not uniform we must expect to have strong and also weaker places. When it comes to a process of treatment by immersion in a liquid like glycerin, it becomes then difficult to discover why a uniform process with uniform results should not be attainable.

### DISCUSSION.

The CHAIRMAN said that the subject of the tempering and hardening of steel was one of those obscure questions lying on the border-land of chemistry and physics, which recent discoveries had thrown some light on, but which were still most difficult to deal with. The consideration of how far this particular process was likely to be successful in overcoming the difficulties of the problem, he must leave to those members, several of whom were present, having that special experience which would enable them to decide.

MR. A. H. ALLEN found it difficult to understand why there should be any great difference in the behaviour of steel when cooled by immersion in glycerin and when cooled by immersion in oil, which was the ordinary method of proceeding. He would have expected that all that was required was a viscous liquid with a high boiling point; and that so long as the necessary condition of viscosity or mobility was secured, it would not matter much whether the steel was hardened in glycerin or oil, or other suitable liquid. He desired to protest against what he considered a misuse of the term tempering. He understood Professor Smith to use that term to express the process of dipping or immersing the hot steel in glycerin or other liquid with a

view to produce a *hardening* effect. It was usual, however, to restrict the term tempering to that *softening* by moderate heating, which was carried out *after* the hardening—to *reduce* the hardness. It might be that the tempering or softening process was prevented from going too far by again immersing the steel in water or other liquid, but this could not be considered essential except in a supplementary sense, and was not tempering. If the author had made his steel as hard as he could by sudden cooling, and had then heated it up in glycerin, instead of relying on the film produced on the surface or other indication that the requisite temperature had been attained, that might have been called tempering. As used in the paper, the term was likely to cause confusion, and he hoped, therefore, that Mr. Smith would modify his use of it before it was printed.

Mr. WATSON SMITH desired to remind the meeting that, in communicating Captain Feodosieff's results, he was in a position of some difficulty, especially with respect to the terms employed. For that reason he had begun the paper with the definition of hardening and tempering given by Professor Roberts-Austen. He was at a loss to know how he could, with propriety, make any radical alterations in Captain Feodosieff's own statements.

Mr. BERTRAM BLOUNT thought that some attention should be paid to the fact that the steel treated by the author of the paper was not of normal composition, but contained chromium. Reference to the peculiar properties of such steels had been made by Mr. Arnold, of Sheffield, in a paper read before the Institution of Civil Engineers last year, on the subject of the use of steel for railway tyres. Mr. Arnold had, if he remembered rightly, found that for producing a steel moderately hard, and free from tendency to failure, it was safer to use chromium than to increase the percentage of carbon. But such a steel as that could hardly be compared with ordinary steel. Another point that had occurred to him was that these highly conductive—or, rather, high boiling point—liquids, though distinctly of use, should not be necessary in the hands of any workman of ability. It had been said that a man who could not temper steel with fire and water merely ought to abandon the trade.

Mr. JOS. BERNAYS said that he had had some experience in the hardening and tempering of steel. Tempering could be done in various ways; and he agreed with Mr. Smith's definition of it as a slighter reheating of the steel, and plunging it into a liquid. The process was so carried out in every smith's shop in the making of tools, and similar articles of steel. They were first heated and made thoroughly hard; then they were heated again to a lower temperature, and were then again plunged into water for thorough cooling. He would not say that tempering might not be done in other ways; but the method he had described was the one usually followed in an engineer's shop. He had done the operation frequently himself, and had by it produced a proper temper in steel tools, springs, &c.

Mr. A. H. ALLEN inquired which operation was considered by Mr. Bernays to be tempering—the warming up after hardening, or the plunging into water afterwards?

Mr. BERNAYS replied that both were necessary, that the steel was first heated to redness, and plunged into cold water or oil for making it hard. It was, however, not quite cooled down. The inside of the steel was left hot, and a bright spot was then filed at the part to be tempered. As the surfaces were getting reheated from the inside, the bright part assumed various colours, first, pale straw, then pale blue, and lastly dark blue, according to the heat transmitted from the interior. As soon as the right degree was arrived at, the steel was again plunged into water and thoroughly cooled, and was then in the condition of "tempered" steel.

Mr. ALLEN asked whether the last operation was considered essential for any purpose besides getting the metal cooled quickly and conveniently.

Mr. BERNAYS said it was necessary to prevent the metal getting still hotter.

Mr. ALLEN feared that Mr. Bernays and he were speaking of different things. Mr. Bernays was probably referring to large bodies of metal, whereas he was considering small articles, in which case any final artificial cooling to prevent spoiling of the temper already attained was unnecessary.

Mr. BERNAYS replied that he was speaking of articles of the size of the samples before them, which had a considerable thickness. They might be reheated in a different way, by bringing them to an external source of heat.

Dr. SQUIRE wished to point out, with respect to Mr. Allen's remark, that the process described in the paper was not under the same conditions as the method of tempering by means of oil. There was a difference which might perhaps be of importance. The specific heat of glycerin was higher than that of oil; and, moreover, he understood the author to say that the glycerin might be mixed with more or less water, by which its specific heat would be further increased. The greater the specific heat of the liquid into which the steel was plunged the more rapid would be the cooling; so that the dipping into glycerin more or less diluted appeared to be a sort of halfway method between dipping into water and dipping into oil.

Mr. ALLEN said that was true.

Mr. E. RILEY said that Mr. Hadfield, who was present, would probably be able to tell the meeting something about the effect of adding chromium to steel. He might say, however, that its use had been known for 12 years past. Hundreds of tons of chromium iron had been used for making axles at Messrs. Brown, Bayley, and Dixon's works, because it was found that the addition of a little chromium pig to the steel enabled it to stand a very severe falling weight test. That was in 1878 or 1879, and the fact was then a trade secret.

Mr. R. A. HADFIELD feared that he could not give the meeting much information as to the effect of chromium on steel. His own experiments indicated that combination of chromium and iron only did not give hardness, and that the prevailing impression that they did was a wrong one. Carbon alone seemed capable of giving the hardness to iron, that is to the material termed "steel"; and unless carbon was present, chromium was no more effective than manganese, silicon, or other element. Perhaps it might be well for the author to know that the results he had quoted as to tests of projectiles were very different from those required by our own War Office. A 12-in. shell penetrating a 16-in. plate would not be considered sufficient by our Government. They would require it to pierce something like 20 inches of compound steel and iron plates—which was a severe test. Thanks to the assistance which the Government was now giving to English manufacturers, they were accomplishing similar results, equal and superior to those of foreign makers. A short time ago his firm, Hadfield's Steel Foundry Co., Limited, had sent two 6-in. shells through 9-in. compound plates and 8 ft. into the wood backing, and both shells were practically undamaged. It was satisfactory to know that his own firm and other English makers had been able to fulfil the requirements of the War Office, and equal foreign productions. There was considerable misconception as to the definition of the word "tempering." He thought that Mr. Allen was perfectly right in his view, and that hardening must be defined as a distinct process and not mixed up with tempering. Probably the error was partly explained by the fact that the French always use the word "*tremper*" to indicate hardening; thus the English and French expressions had got mixed and led to this prevalent misconception. Hardening, he thought, must be defined as the turning of the carbon from the state in which it was found in unhardened metal into the hardened compound, in which form it would scratch glass; if this result was not attained then the term "hardening" could not be applied. Tempering in all Sheffield trades meant a subsequent and separate operation or reheating and reduction of hardness. The form of that compound was not known at present, but thanks to the experiments of scientists much was being

found out about it. In the meantime it would be best to stick to the good English word "hardening," which clearly defined the operation. Tempering was a different process altogether.

Mr. E. RILEY quite agreed with Mr. Hadfield as to the effect of chromium. His firm had used it in the manufacture of soft steel, because they had found that it increased the tensile strength of the metal without increasing its hardness. It was expensive to use, however, and so they did without it as far as possible.

Mr. R. A. HADFIELD said that it was a striking instance showing how men's minds in different parts of the world unconsciously worked on the same idea, that experiments had been made in America within the last two years in the same direction as the process now described by Professor Smith.

## BROMANIL.

BY S. M. LOSANITSCH.

*Professor of Chemistry in the Royal Serbian Academy.*

IN a communication on the action of nitric acid on ordinary tribromaniline, melting at  $119^{\circ}\text{C}$ , I have shown that in the reaction which takes place along with a certain amount of other products, bromanil is produced in considerable quantity (about 10 per cent.) (Ber 15, 471).

This reaction for the formation of bromanil is important, since by its aid the pure substance can be easily prepared. It is only necessary to boil the tribromaniline with strong nitric acid till the decomposition products (dibromdinitromethane and tetrabrombenzene) have distilled over, afterwards washing the residue with hot alcohol, in order to obtain bromanil in pure golden-yellow crystalline plates. In the investigation referred to, I have thus obtained several hundred grammes of pure bromanil as a by-product, and this material served for the further study of bromanil.

*Bromanil* is easily soluble in hot benzene, and tolerably soluble in glacial acetic acid, but almost insoluble in alcohol. According to an earlier report, it is considerably soluble in boiling alcohol (Ann. 143, 255; 91, 307; 205, 53), but this is to be ascribed to the presence of impurities.

In the analyses, the bromine found was in one case 75.30 per cent., and in another 75.45, the calculated amount for  $\text{C}_6\text{Br}_2\text{O}_2$  being 75.47 per cent. The product obtained was therefore a pure bromanil. It crystallised from glacial acid in shining rhombic plates of a sulphur-yellow colour, and from benzene in thick dark yellow plates. By letting hot under-saturated benzene solutions of the substance stand in beaker glasses for some time, I succeeded in obtaining perfectly formed crystals of bromanil.

From such a solution, after some days, beautifully developed crystals were obtained, and these were crystallographically examined by my friend Professor A. Arzruni. He states that "bromanil crystallises in the monoclinic system. The crystals are of an orange-yellow colour (corresponding to the tint 4 K. of Rüdke's colour scale by incidental, and 6 N. to 7 N. by transmitted light), and they are very lustrous.

"The forms observed are (001), (110), and (101), which all exhibit very even surfaces.

"The crystals are, without exception, twins upon the face (001).

"The fact has been deduced by repeated experience, and in such crystallisation no sensible disturbance in the formation and angle values were observed. This is shown in the following table:—

		Measured.	Calculated.
110	110	$73^{\circ} 29'$	..
110	001	$86^{\circ} 46'$	..
110	$\bar{1}\bar{1}0$	$18^{\circ} 24'$	$18^{\circ} 28'$
001	$\bar{1}01$	$77^{\circ} 58\frac{1}{2}'$	..
$\bar{1}01$	$10\bar{1}$	$24^{\circ} 8\frac{1}{2}'$	$24^{\circ} 7'$

"The values prefixed by an asterisk above lead on calculation to the axis relationship:— $a:b:c = 1.3905:1.2:9335$ , and the axial inclination  $\beta = 74^{\circ} 26\frac{1}{2}'$ . A very complete cleavage is manifested in a direction parallel to (001). The plane of the optic axis coincides with that of the symmetrical axis."

Bromanil is not soluble in concentrated sulphuric acid, but on long boiling it dissolves slowly with liberation of bromine, and is converted into a dirty red crystalline powder. This powder consists of bromanilic acid. I have investigated two salts of this acid. The silver salt,  $\text{C}_6\text{Br}_2\text{O}_2(\text{OAg})_2$ , separates as a dark red amorphous precipitate on the addition of nitrate of silver to the aqueous solution of the acid. The percentage of silver found in this salt was 42.19, whilst the formula given requires 42.19 per cent. The barium salt,  $\text{C}_6\text{Br}_2\text{O}_2\text{Ba}$ , separates as a brown crystalline powder when bromanil is boiled with an aqueous solution of barium hydrate. This powder dissolves in boiling water slightly acidulated with hydrochloric acid, to which it communicates a violet colour, and from this solution the barium salt separates in brown prisms grown together in the form of crosses. In this salt 31.15 per cent. of barium was found, the formula demanding 31.64.

*Anilide of Bromanilic Acid*,  $\text{C}_6\text{Br}_2\text{O}_2(\text{NH}\cdot\text{C}_6\text{H}_5)_2$ , separates in shining rhombic plates on adding aniline to a boiling solution of bromanil in benzene or glacial acetic acid. These crystals have a beautiful bluish-violet colour in reflected light, and appear yellow by transmitted light. The compound was first prepared by Stenhouse, and according to him, it crystallised in black tables (Ann. Suppl. 8, 22).

*Toluide of Bromanilic Acid* (ortho and para).—

Ortho and paratoluidine combine with bromanil to form these toluides when they are boiled with benzene or glacial acetic acid.

The *ortho-toluide* separates in dirty yellow, the *para-toluide* in dark red rhombic plates. The latter compound appears yellow by transmitted light. Both these toluides are dissolved by benzene or glacial acetic acid, yielding yellow solutions. The *ortho*-compound is more easily soluble than the *para*. The nitrogen was determined in these compounds, and found to be 5.92 and 5.89 per cent. respectively, the formula demanding 5.88 per cent.

*Xylide of Bromanilic Acid*,  $\text{C}_6\text{Br}_2\text{O}_2[\text{NH}\cdot\text{C}_6\text{H}_3(\text{CH}_3)_2]_2$ . The benzene solution of the bromanil turns brown on addition of xylidine (ordinary). This solution was evaporated to dryness, and the residue dissolved in glacial acetic acid. From the solution the xylide crystallises in yellow plates. Nitrogen found = 5.3 per cent.; the formula requiring 5.56 per cent.

## DISCUSSION.

On finishing the reading of the communication, Mr. WATSON SMITH said that the only indication he could at present see of the practical application of bromanil was the possibility of its being used in the manufacture of colouring matters. But unless its use was found to constitute some considerable improvement on Chloranil blue, he feared that there was not much chance of its employment even in that direction. Chloranil was produced very cheaply at present by the reaction of potassium chlorate and hydrochloric acid on pure phenol. The chloranil thus formed combined on heating with the aromatic tertiary amines, yielding a fine blue colour, or by heating with benzyldiphenylamine, a fine green colouring matter was obtained. Whether it might be possible by substituting bromanil to produce an analogous variation of shades such as were obtained, for example, in the Eosin group, where, by brominating fluorescein the tetra-brominated product (ordinary Eosin) of yellow shade is formed, or by iodising the tetra-iodo-compound (erythrosin) of blue shade, would be obtained, only actual experiment could decide.

The CHAIRMAN said that he would be a bold man indeed who should say of any given process that it would never become valuable in technical chemistry. Remembering an instance

in his own student days, when some carbolic acid was required and there was nothing to prepare it from except the alkaline washings of some coal tar—he was never surprised to find chemical rarities of a few years back becoming the common productions of to-day. A purely scientific paper of to-day might in a few years hence be the source of a valuable chemical industry: and therefore such papers should be regarded with respectful, if not active, interest.

Mr. A. R. LING wished to draw attention to the fact that he had described a method in the Chemical Society's Journal, 1887, 148, by which bromanil could be obtained in theoretical quantity. This consisted in heating dibrom-*ortho*- or dibrom-*para*-nitrophenol with bromine and water, the reaction being represented by the following equation:—

Since dibrom-*ortho*-nitrophenol could be readily obtained by nitrating crude dibromophenol (from phenol and bromine), this method appeared to him to be worthy of attention, should bromanil become of technical importance. With regard to bromanilic acid the constitution of which had recently been determined by Hantzsch—to the other compounds mentioned in the paper, he thought that they had been already fully described by Stenhouse and others.

Meeting held Wednesday, January 15th, 1890.

DR. F. HURTER IN THE CHAIR.

### NOTE ON A GLASS TOWER CONDENSER.

BY DOUGLAS HERMAN.

As having some relation to the principal business of this evening—the discussion of Dr. Hurter's masterly paper on the "Condensation of Hydrochloric Acid Gas"—I thought it might be of interest to the members to see how a tower condenser can be made practically entirely of glass.

In the laboratory, for the condensation of acid or corrosive gases (except of course in the case of fluorine), no chemist probably would think of using any other material than glass, its superiority being so manifest. On the large scale,

however, especially where it is desired to employ a tower filled with some material exposing a large surface, the difficulties in the way of employing glass are great, as a fracture in the lower part of the tower caused by the pressure of any considerable height of packing material or otherwise, might empty the tower of its contents. If the glass walls of the tower were made sufficiently thick to be reasonably safe against such an accident they would be very costly, besides being liable to fly with changes of temperature. Moreover, one of the principal advantages to be derived from the use of glass, namely the cooling effect arising from the thinness of the material, would be to a considerable extent neutralised.

In the apparatus before you an attempt has been made to overcome these difficulties, with what probability of success I must leave it to members to determine who have far more practical acquaintance with the subject of the condensation of acids, &c., than I can pretend to.

The principle adopted is to divide the vertical height of the tower into sections of two or three feet, so arranged that each section shall carry the entire weight of packing material contained within it, without in the slightest degree pressing upon the portion of the tower below it. A dangerous pressure in the lower parts of the tower is thus avoided, and the tower may be built to any height that is considered desirable.

The principle of sub-dividing the weight is carried into effect by providing slightly tapering glass pipes, *a*, with an upper external and lower internal flange, of the form shown

in section at *b* and *c*. The upper flange, resting upon suitable supports, *e, f, g*, carries the whole weight of the pipe with its contents. A grid, *d*, supported by the lower internal flange, carries the packing material. The pipes being slightly taper, the lower portion of one pipe fits into the upper portion of the pipe immediately below it, and the joint is made good with any suitable cement. Flanges of the form shown, in addition to serving the purposes described, materially add to the strength of the pipe.

Bends to connect one tower with another can be made of glass, but it is practically impossible to make large tees of this material, and where such connexions are necessary, earthenware should be employed. If desired, the bottom pipe of each tower may be made funnel-shaped to facilitate the conveying away of the liquid product.

The grids, *d*, supporting the packing material are composed of strips of glass,  $\frac{3}{8}$  in. thick by  $1\frac{1}{2}$  in. deep, and to prevent the liquid trickling along these to the sides of the tower, they are cut with a slight curve, from the lowest part of which the liquid has a tendency to drop. By placing the grid in one pipe at right angles to that in the one immediately above it, the centre of distribution of the descending liquid is continually changed from pipe to pipe.

The packing material may be glass, and if in the twisted irregular form here shown, will weigh, with the supporting grid, about 1 cwt. per pipe.

If sufficient taper is given to the pipes, and care is taken not to overfill them with packing, a damaged or obstructed pipe may be lifted out and another one substituted, without interfering with the rest of the tower.

The pipes are made about  $\frac{1}{8}$  in. thick, and in point of price will compare favourably with earthenware, doing the same amount of work.

Whatever the practical value of such an apparatus may be—and it is perhaps better adapted for the preparation of pure acids, &c., than for the condensation of the crude hydrochloric acid of alkali works—it certainly satisfies one of the requirements insisted on by Dr. Hurter as necessary for successful condensation, namely, that of providing “ample cooling surface in that part of the apparatus in which the gas comes in contact with the condensing liquid.” Each pipe of the size shown has a capacity of about 3 cub. ft., and a surface area of over 9 sq. ft., or say 3 ft. of surface to one of capacity. In the stone condenser, 40 ft.  $\times$  8 ft.  $\times$  8 ft., employed by Dr. Hurter in some of his experiments, the relation of vertical surface to capacity is only as 0.5 : 1, and the sides of course are enormously thicker in the case of stone than in glass.

### A QUALITATIVE TEST FOR GLYCEROL.

BY CHARLES A. KOHN, B.Sc., PH.D.

*Demonstrator of Chemistry, University College, Liverpool.*

Is the following qualitative test for glycerol advantage is taken of two characteristic reactions:—

(1.) The formation of acrolein by the distillation of glycerol with acid potassium sulphate, according to the equation:—

(2.) The red colouration produced with a solution of rosaniline, decolourised by sulphur dioxide, by acrolein, as by all aldehydes (Schiff and Caro's reaction).

To carry out the test the solution containing the glycerol is evaporated down to about 5–10 cc. in a small porcelain dish, about 1 gm. of powdered acid potassium sulphate added, the whole well mixed together and then taken to dryness on the water-bath. The residue is transferred to a hard glass tube, 3–4 in. long, fitted with a cork and exit tube, the latter passing into a test tube containing water. On heating the tube the acrolein is readily evolved and is dissolved by the water in the test-tube; the contents of the latter can then be tested for the presence of an aldehyde in the usual way by the addition of a few drops of Schiff's reagent. Both before and after the addition of the reagent the solution in the test-tube should be well shaken; the colour only develops slowly and reaches its maximum after 15–20 minutes standing. If the aqueous solution happens to have got warm by the condensation of steam evolved during the distillation, it must be cooled before adding the reagent, since the latter turns red on warming in the absence of an aldehyde.

The delicacy of the reaction has been tested by Mr. J. T. Conroy, B.Sc., and Mr. B. W. Jones, with the result that it is possible to detect 0.015 gm. of glycerol in this way: or in round numbers, 1 part of glycerol in 650 parts of water, by evaporating down 10 cc. of the solution, and therefore 1 part of glycerol in 6,500 parts of water by evaporation down 100 cc.

The reaction is not given by any of the following substances: Mannite, cane sugar, grape sugar, milk sugar, starch, dextrin, albumen, gelatin, stearic acid and oleic acid; but the carbohydrates interfere with the delicacy of the test owing to the fact that their distillation products with acid potassium sulphate hinder the formation of the red colour with the rosaniline solution. To carry out the test in presence of sugar, the latter must first be removed by evaporating the solution in the presence of calcium

hydrate and sand or of calcium hydrate and calcium carbonate, and extracting the residue with a mixture of 2 parts of alcohol to 1 part of ether. On evaporating this extract with acid potassium sulphate and distilling the residue, the reaction is obtained as above, but it is not possible to detect less than 0.03 gm. of glycerol in the presence of much sugar, or 1 part of glycerol in 3,300 parts of water by evaporating down 100 cc. of the solution.

The reaction must be similarly applied in testing for glycerol in wine and in beer; the limit of its delicacy in these cases is the same as above. In testing milk for glycerol the casein, albumen, and sugar should be first removed.

Fatty acids do not interfere with the delicacy of the reaction.

Compared with other colour reactions for glycerol, this test appears more characteristic, though not quite so delicate as Reichel's phenol test (this Journal, 1882, 202). It is considerably more delicate than Reichel's pyrogallol test (this Journal, 1883, 356), and also more delicate than the borax test (Senier and Lowe, J. Chem. Soc. 1878, 401).

Mr. E. CAREY asked whether it would not be possible to apply the test for the quantitative determination of glycerol colorimetrically?

Dr. KOHN replied that this might be done as long as only small quantities of glycerol were concerned, but he did not consider that the depth of colour obtained would serve as a quantitative reaction when the tint first got was a fairly deep one, even if dilution were resorted to for comparison.

### ADJOURNED DISCUSSION ON DR. HURTER'S PAPER ON THE CONDENSATION OF HYDROCHLORIC ACID GAS.

(See Journal, VII., 861–67.)

Mr. A. E. FLETCHER said he had read the paper by Dr. Hurter with great interest. His own experience had led him to advocate largely what Dr. Hurter had pointed out, viz., that condensers should be kept cool. It was of great importance to abstract the heat which was generated by the act of condensation. A question might arise as to the wisdom of using capacious coke towers as condensers, as being likely to retain the heat of condensation, but probably the reason why such large vessels were used was that the supply of hydrochloric acid was intermittent. A large massive coke condenser acted both as a condenser and a water receiver. The supply of hydrochloric acid was intermittent, and at the time the gas approached the condenser the latter was nearly full of almost clean water. The gas attacked it at the bottom and gradually gained on the water supply, which was constant and slow. It might reach near the top of the tower, but before it did so the supply of acid diminished, because the charge in the decomposing pot was getting spent; then the water gained on the hydrochloric acid, thus preparing the tower to receive the next charge of acid gas. He thought that was the *raison d'être* of large condensers, otherwise it would be much better to have smaller vessels, such as pipes and tanks.

There was an interesting passage in the paper calling attention to the fact that air, passed through hydrochloric acid of 12° Tw. would come away with about 0.2 gm. HCl per cubic foot. This did not, however, affect the question of condensing, because the top of the condenser, being filled with clean water, the hydrochloric acid came in at the bottom and passed away from the top. The solution of HCl thus became weaker as it rose up in the tower.

A point of practical importance in the condensation of hydrochloric acid not mentioned in the paper was the difficulty of wetting particles of matter when disseminated through a gas, producing a sort of acid fog. The hydrochloric acid must be supposed to be condensed already, but the

difficulty was to precipitate it. If they put some water into a bottle containing vapour of HCl mixed with air, it needed much shaking of the bottle to induce the water to take up the fine particles of hydrochloric acid. So in condensing, the great difficulty was to produce contact between the fine particles of acid and water. If this did not exactly come within the scope of the paper, yet being closely associated with it, he thought some attention might be given to the point.

Mr. R. F. CARPENTER had read the paper with extreme interest, and had worked out the calculations in Dr. Hurter's examples, so that he might thoroughly grasp the points Dr. Hurter desired to emphasise. In doing so, he had found two or three things that required correction.

On p. 863, second column, the number of units of heat given out by the condensation of 501 lb. HCl was given as 192,384. The strength of the acid condensed was not given, but this must be, if the heat units are correctly stated, higher than 36° Tw., and it is certainly doubtful, if on the large scale an acid stronger than 36° Tw. can regularly be obtained. Following on to p. 864, second column, in the example where percentage of HCl is 14.1, H<sub>2</sub>O, 15.1, &c., and  $x_0$  of the formula is given as 0.206, this should certainly be 0.151, as given correctly a few lines lower down.

He was much interested in the examples given by Dr. Hurter of the amount of condensing work done in the cooling pipes, as he had taken part, 12 or 14 years ago, in experiments on the large scale, having for their object the production of dry hydrochloric acid gas. With that view the salt used was subjected to a preliminary drying, and as strong an acid as possible was used, the gases mixed with air being cooled in glass pipes to air temperature. He was much surprised at the amount of hydrochloric acid removed from the gaseous mixture, 25 to 30 per cent., confirming the example given on p. 863, second column.

Dr. Hurter had given a most valuable contribution to forming a theory of condensation of hydrochloric acid, and it seemed to him that he had not left much for anybody else to add. From what Dr. Hurter said on pp. 865, 866, the technological books treating of heat required corrections from the extraordinary differences that were to be found between the rates of conduction of stone stated by certain authors and that proved to have taken place by Dr. Hurter in his stone condensers.

Mr. HIGGINS said that, in accordance with Dr. Hurter's request, he had done his best to pick a few holes in the paper. In the second paragraph, on p. 864, he thought the amount of steam condensed,  $V_0r_0 - V_1r_1$ , was wrongly stated.

Again, in calculating the radiation from the condenser, its temperature was taken at 80° C., which was the temperature of the acid at the bottom. He should like to ask whether that represented the average temperature of the whole condenser. On reference to Table I., it would be seen that, when the acid reached 12° Tw., it would be about 80° C., but the question was how far down the condenser the acid had to go before it became 12° Tw.

Besides Dr. Hurter's question "What is the strongest acid that can be produced from a gas of a given composition?" there was another to be solved by the manufacturer, "What is the strongest acid that can be produced from a gas varying much in composition, at one time nearly pure, at another nearly free, at one time dry, at another drenched with steam?"

Dr. HURTER, in reply, said he was very much pleased with the attention which had been paid to his paper by various readers at home and abroad. He thanked Mr. Fletcher and Mr. Carpenter for their kind remarks and criticisms. Mr. Fletcher had said that the paper might have dealt somewhat with the difficulties of complete condensation, but that was not within the scope of the particular paper, which was written entirely from the manufacturer's point of view. He felt certain that there was no one so competent to write a paper on the difficulties of complete condensation as Mr. Fletcher, who had not only a much longer but also a very much wider experience.

With regard to the errors which Mr. Carpenter had pointed out, the first example was one transferred from his note-book to this paper without revision, and referred to 36° Tw. acid. It did not agree quite with his tables, because it was worked out before he possessed these tables. The error was of no great consequence. If the tower had made 30° Tw. acid instead of 36° Tw., the example would be altered as follows:—

For condensation of steam .....	41,808
" " 501 lb. acid .....	205,452
Total .....	247,260

and the pipes would have done 54.6 per cent. of the work instead of 56 per cent., as stated in the paper.

As regards the second error, p. 864, the value of  $x_0$  was incorrectly stated; instead of 0.151 it was given as 0.206, but the example was correctly calculated with 0.151.

In reply to Mr. Higgins, the amount of steam condensed was correctly stated on p. 864, and was  $V_0r_0 - V_1r_1$ . There was, however, an error of omission in the text. The symbol  $x$  was not correctly explained. He had said, "For, if the volume  $V_0$  of a gaseous mixture of hydrochloric acid, air and steam containing  $x$  volumes of steam," &c., but he ought to have said "containing  $x$  volumes of steam per unit volume of the gas." That would at once explain the formula, and indeed the subsequent examples did supply the omission.

With respect to taking the temperature of the liquid within as the average temperature of the condenser, he had done that after mature consideration. At first he used to average the temperature of the water going in and the acid coming out, but that proceeding gave such enormously high figures for the heat-conducting power of the stonework, that he was driven to the conclusion that the average temperature within the condenser was greater. To the same conclusion he was driven by the fact, that although the gases passed through cold water at the top of the condenser, they came out hot. In the first example he gave of a stone condenser the gases came out at 60° C. It was clear from that that a great deal of the condensation is effected only at the very top of the tower, and when considering Table I. it would be seen that water of 15° C. could be heated to 60° C. by forming acid of only 7° Tw. With some form of spray condensers the temperature of the gases was frequently greater on leaving the condenser than on entering. All these considerations led him to the conclusion that rapid condensation occurred at the top, and that the condensation in the lower portions tended to keep up and increase that temperature, and it was more probable that the average temperature of the condenser was higher than the temperature of the acid flowing out.

With regard to the varying conditions occurring in the works, he did not think he could be expected to give formulæ which would deal exactly with every variation. The figures in his examples were all averages over one or two charges. There was one more blunder in the examples which needed explanation. The example on p. 866, second column, was also one from actual practice, and was wrongly copied. The difference of temperature between air and condenser was stated as  $65 - 15 = 50$ . The real difference was obviously 50°, but the example was worked out with 40°, so that the amount of hydrochloric acid of 30° Tw. should be certainly obtained in practice. The use of 40 instead of 50 was simply the application of a factor of safety.

He said in his paper that he thought it would be difficult to test the formula by small scale experiments, but since then it struck him that it could be tested by passing air at different temperatures through acids of various concentration at various temperatures, and thus to obtain some verification. He had made two such experiments, of which he appended the results.

*Experiment 1.*—Air in fine bubbles was passed through liquid acid containing per gramme of water 0.419 grm. HCl, at a temperature of 55° C. and at 765 mm. barometric pressure. (Acid = 29.5° Tw.)

The temperature of the gas was kept constant by a water-bath, and the gas at that temperature brought into

contact with concentrated sulphuric acid to absorb the steam. The HCl gas was then absorbed in water, and estimated by titration. The increase of weight of the sulphuric acid, after deducting from it the HCl absorbed by the sulphuric acid, gave the water carried over.

The results of the analysis were:—

	By Formula.
Air.....	82.76
HCl.....	10.67
H <sub>2</sub> O.....	6.52

2.—A similar experiment, made with acid of 25 Tw., 0.333 grm. HCl to 1 grm. of water at 83° C. and 751 mm. barometric pressure, gave—

	By Formula.
Air.....	60.97
HCl.....	11.42
Steam.....	27.61

It would be seen that the greatest error lay in the steam, not in the hydrochloric acid; a slight error in temperature would seriously affect the amount of steam.

The calculated results were obtained from the formula—

$$P = \sqrt{\frac{0.15}{0.3040 - 0.0016 t}}$$

putting for C 0.419, and for t, the temperature, 55, they calculated the partial pressure of the hydrochloric acid to be 82.8 mm. and from Table II. the tension of steam was found to be 63 mm. The barometer being 765 mm., the partial pressures are—

	Per Cent.
Air.....	605.2 or 80.95
HCl.....	82.8 or 10.82
Steam.....	63 or 8.23

And a similar calculation would give the results as shown for the second experiment.

He wished, in conclusion, to remind them that whatever merit there might be in adapting Roscoe and Dittmar's results to the wants of the manufacturer, the great credit belonged to those investigators for supplying the accurate facts needed for the adaptation.

Meeting held on Wednesday February 5th, 1890.

DR. F. HURTER IN THE CHAIR.

## A NEW FORM OF SPRENGEL PUMP, AND APPARATUS IN CONNEXION THEREWITH.

BY SIDNEY G. RAWSON, D.S.C., F.I.C.

*Demonstrator of Chemistry, University College, Liverpool.*

ANYONE who has used an ordinary Sprengel pump will know that the gas from the vessel which is to be exhausted is removed by small pistons of mercury. These rapidly succeed one another in the barometric fall tubes, and portions of the gas are trapped, and carried away between each two of these pistons. When the exhaustion is approaching completion, the volumes of gas so removed become exceedingly small, and the last portion of the process is then one of increasing slowness. The newer forms of pumps work on another principle. The mercury in them is caused to issue in the form of a fine jet or spray, and the molecules of the gas are, as it were, driven forward and caught by the mercurial bombardment to which they are subjected. They are then trapped by the pistons of mercury which form in the ordinary way lower down in the fall tubes.

This form of pump is divisible into two main kinds, viz., the one in which the jets of mercury issue in a horizontal plane as figured in Gillingham's paper (this Journal, III., 83), and the other in which the mercury flows from the commencement in a vertical direction, as in Fig. 1.

Fig. 1.

Of these two modifications, I prefer the latter, and for these reasons:—If the mercury issues horizontally, it is somewhat difficult to so place the jets that the streams of mercury shall exactly impinge on the mouths of the tubes. Unless the pump is well made, they will either strike too high or too low, and further, unless there is a considerable pressure of mercury, the jets may not carry even so far as the bounding walls of the exhaust chamber, then the lowest tube receives an excess of mercury, and becomes choked.

In the second form of pump, if the fall tube is slightly opened at its origin, the mercury can only run down that fall tube opposite to its own supply jet. This latter form is also more readily made, and especially is this the case as the number of fall tubes increases. The peculiar mercury distributor of this pump we owe to Nicol, though it had been used by myself some time before the publication of his paper in the British Association Reports for 1887.

My own form of this pump differs somewhat from Nicol's in the following respects. I seal the fall tubes to the pump

Fig. 2.

head, and use no india-rubber as a connexion (see Fig. 1, A), thus doing away with all chance of leakage. The mercurial supply tube, within the exhaust chamber in his pump, ends freely, and in the same horizontal plane with it is the exhaust tube. This, to my mind, would impose rather a strain on the tube from the leverage of the mercury, and I have therefore always sealed the tube to the wall (Fig. 2, A), and so placed my exhaust tube B that it opens in from above. The fall tubes are also sufficiently long to enable me to collect the gases which are exhausted. All these are, however, minor differences.

It will be found that if a pump has been working for some time the fall tubes always become coated inside with a thin

film, possibly of oxides of foreign metals. The mercury which I use I have had distilled two or three times, and one would feel inclined, therefore, to say that it was quite pure. But even with this pure mercury the deposit, though it formed very slowly, always made its appearance in the end. Small air bells or bubbles cling most obstinately to this film, and hence it becomes a matter of some importance to be able to remove it easily, and without stopping the pump. For this purpose the small funnel C, is attached to the pump. Usually this is kept filled with mercury, but when necessary, a little sulphuric acid is poured on the mercury, and the plug D, which is ground in, is gently raised, and the mercury, together with a portion of the acid, is allowed to run into the distributor, and thence into the fall tubes. The plug is replaced, and a little more mercury poured in. I have found sulphuric acid very good for this purpose. Professor Ramsay recommends the use of the vapour of glacial acetic acid as a cleansing agent.

This pump is a very excellent one and of great power. If only three fall tubes are required their free ends can be easily bent up so that they shall all deliver their gas together; this becomes more difficult as the number increases, but if mere exhaustion be required other tubes can be added with ease.

While experimenting with this pump I devised the very simple form which is shown in Fig. 3. A piece of ordinary pump-tubing some 50 ins. in length is taken, and about

Fig. 3.

10 ins. from the one end a small bulb is blown. There is then sealed into this and projecting into the cavity a small glass jet, about a quarter of an inch in length and of exceedingly fine bore, with the nozzle pointing inwards. It will be noticed that whilst in the other forms the feed-jets of mercury are detached from the fall tubes, here each fall tube carries its own jet, the arrangement being very compact.

The rate at which the feeding-jet will supply mercury entirely depends on the depth of the mercury in the exhaust chamber, and therefore on the length of the tube lying above the bulb. By regulating this depth the pump can be caused to work more or less rapidly as may be required, and this without any contrivances in the shape of taps, &c. There is further a very thorough division of the mercury in the little trapping bulb, for the fine jet of mercury, which is under considerable pressure, impinges strongly on the opposite wall, and is there broken up, filling the bulb with a shower of mercury drops. Possibly this effect might be increased if two feed-jets were sealed into the bulb. I have found it more advantageous to replace the piece of pump-tubing above the bulb by some of considerably wider bore and thinner walls; the difficulties of exhaustion are increased if the molecules of gas have to travel along capillary tubes.

Though two or three fall-tubes of this description can be sealed into a glass exhaust chamber, it is a somewhat difficult task. Unless an extreme amount of accuracy in the volume of gas to be collected is required, it is quite sufficient to take a piece of wide glass tubing which is strangled at either end so as to firmly hold the rubber corks with which it is to be closed. Through the lower cork passes the pump and fall tube combined, and through the upper the mercury feed-supply and the exhaust tube. From some experiments which I have made I agree with Gunningham (loc. cit.) that the diameter of bore of the fall tubes should be about 1.6 mm., and the length about 1 metre, reckoning from the level of the mercury in the lower reservoir to the mercury feeding-jet. In longer tubes than this the mercury falls with much force, and the incessant hammering which goes on is apt to cause the tubes to crack; several have been thus rendered useless in my hands.

In working with exhaust pumps there is usually some difficulty in making an air-tight joint between the pump and the apparatus which is to be exhausted. Of course the most effectual and certain way is to unite the two ends by an actual glass seal, but in many cases this is by no means easy, and when made successfully it has the disadvantage of converting all the different portions into one solid rigid whole. Professor Crookes uses very thin spiral glass tubes to unite the various pieces, and these from their elasticity do allow of there being a certain amount of play, but the glass seal, and with it considerable experimental skill, is still required.

India-rubber tubing is of very little or no use. All sorts of cements have been tried for this purpose. Thus Professor S. Thompson\* mentions a mixture of Burgundy pitch, 96 parts, with 4 parts of gutta-percha or 1 part of vaseline with 3 parts of paraffin wax. Others are equal parts of beeswax and resin, india-rubber, and many more. I have myself used beeswax and resin containing a little vaseline, but I cannot recommend it highly, though it is as good as any of the others. Paraffin wax, pure and simple, I have also tried and found to work well, but it contracts on solidification, and attaches itself more especially to the glass walls, leaving a fissure between when these are close together, and hence there is always the chance that air may get in. No organic compound can be said to be good, as at high *vacua* they all evolve vapour. As suggested by Professor Thompson in his paper, some experiments were made by me on fused chloride of lead. This only melts, however, at a high temperature, somewhat below a red heat, and at the same time emits fumes. On cooling it contracts considerably and cracks in all directions.

After trying many materials, the following is the cement I now employ, and which is of very easy application. It is nothing but fusible metal containing a considerable amount of mercury. Its percentage composition is as follows:—

	Per Cent.
Bi .....	40
Pb .....	25
Sn .....	10
Cd .....	10
Hg .....	15

\* "The Development of the Mercurial Air Pump." *Journal of the Society of Arts*, 1888. From this paper Fig. 1 is copied.

If ordinary fusible metal be taken it will crack the glass, from the large amount of expansion which it undergoes on solidifying. The addition of a little mercury reduces its expansibility and at the same time lowers the melting point. As it still, however, expands considerably on cooling, it forces itself into every minute crevice, acting as a most efficient cement. It should be applied in a molten condition, and the glass should also be hot, and, before exhausting, the joint should stand for an hour to allow the alloy to become thoroughly set. Tubes cemented to the pump by this compound I have had exhausted for weeks without any sign of leakage. I wish here to express my thanks to Mr. H. S. Marsh for the trouble which he has taken in experimenting with me on these alloys.

I also employ a special form of joint. It is shown in Fig. 4 as in use between two U-tubes which have been

Fig. 4.

taken for drying the gases which are to be collected. Each limb bears a small glass cup A carried on a cork B, through which passes one end of the U-tube. A curved tube C, bell-mouthed at either end, fits in each case outside the free end of the tube but within the glass cup. The molten alloy is poured in almost to the level of the mouth of the U-tube, and on cooling grips the whole firmly together. Until the alloy is poured in there is any amount of play, as can easily be seen, between the different parts of the apparatus, for the bell tubes need not be placed in position until everything else has been finally adjusted.

Moreover, instead of there being a long stretch of U-tubes or other apparatus, these can be ranged in rows of twos or threes, &c., one behind the other, by placing the proper bell-tubes at right angles to the others in that row, and thus making connexion with those coming both before and after.

The apparatus can be readily disconnected by placing round each of the glass cups in turn a brass cup riveted to a rod of the same metal. When the rod is warmed

Fig. 5.

the brass cup rapidly becomes heated and the alloy, as it melts at such a low temperature, is easily liquefied, and the bell-tube can then be lifted out. It will be found more

convenient to have the brass cup in two halves attached to two brass rods as in Fig. 5; it is then more easy to remove it, otherwise, as it must fit close to the glass cup, it will be necessary to wait until the brass cup is cool before it can be bent open.

In some experiments on which I am engaged I have found it necessary to use a particularly formed flask for the preparation of certain gases. A short description of this may prove interesting.

Fig. 6.

It holds about 200 cc. and fitting to the neck and ground to it with the *greatest care* is a glass hollow stopper A perforated in two places. For cement I use a mixture of beeswax, resin, and a little vaseline. Through one perforation B in the stopper passes an inlet tube for acid, terminating within the flask in a tube bent up slightly on itself. Outside the flask it bears a glass bulb into which acid can be poured; the bulb is choked by a ground glass rod, cut into which is a slot, corresponding to one in the bulb. When the slots coincide the acid passes down, but by turning the glass rod through 180° the connexion is cut off. A little acid should always be left in the bulb. Through the other perforation C passes the exit tube, terminating in a bell mouth.

The whole apparatus, from pump to generating flask, it will be observed, is without a single tap of any kind, is air-tight, and yet is readily put together and disconnected, and requires, except in the case of the glass flask, no special skill in its manufacture.

#### DISCUSSION.

Dr. C. A. Koux said he had worked with Dr. Rawson's pump, and could testify to the value of the alloy, which gave very satisfactory results. He would like to ask Dr. Rawson what the efficiency of his simpler form of pump was, as compared with the ordinary forms of Sprengel pump.

Dr. HURTER said that in many of his own investigations he had had many of the difficulties to contend with which Dr. Rawson had so ingeniously overcome. The nuisance of corks and taps in researches where every trace of a gas had to be kept together was very great indeed. He recollected that a few years ago, when he was busy with the investigations of an ammonia-soda process, he had to avoid loss of every trace of ammonia which was evolved at a red heat. He could only do this by sealing the whole apparatus together into one piece, and when he had very nearly finished the apparatus he broke it and had to start again. Fusible metal he had also tried, and to his great grief it broke every

glass he put it into, and he was glad to learn that the addition of a little mercury would correct that property of expansion on cooling just sufficient to make a joint without breaking the glass.

Dr. Rawson said, in reply to Dr. Kohn, that as regarded the working of his new pump, he had tried it under various conditions, and had found that the exhaustion to be obtained with it was quite as good as that with any other pump with which he was acquainted. Fusible metal and glass tubes, though remaining intact for a time, were invariably broken sooner or later.

## HOME-GROWN SUGAR FOR GREAT BRITAIN AND IRELAND.

BY G. SCHACK-SOMMER, PH.D.

The agricultural question is undoubtedly one of the most pressing and vital importance both in England and Ireland. In which of these two countries it is of most immediate moment it is not necessary for my present purpose to inquire; and to go into the causes that have led to this state of things is equally beyond my province or intention. I would merely mention, in passing, that the British Government have thought it advisable to establish a Board of Agriculture, and to appoint Mr. Chaplin as its first president; sufficient proof, if any was needed, that the agricultural interests of the United Kingdom are of importance enough, even in their condition of decadence, to require the attention of a special department. To that special department and to you, members of the Society of Chemical Industry, I have something to say, which I think is worthy of the serious consideration of both.

I ask you why cannot we grow beetroot, and manufacture sugar from it, as successfully as they do in France, Germany, Austria, Russia, Holland, Belgium, and many other countries?

With the fiscal difficulties in the way of doing this I am not at present concerned. My attention has been concentrated principally upon what are supposed to be the natural difficulties of growing sugar beetroot in Ireland or England for the purpose of manufacture, and in this way creating a new industry for both countries. The popular impression has hitherto been that the climate of these islands is too cold and damp for the successful cultivation of sugar beetroot, but I have no hesitation in saying that practical experience has proved the popular impression in question to be entirely wrong and mistaken.

In 1879 a Select Committee of the House of Commons was appointed to inquire into the effect produced upon the home and colonial sugar industries of this country by what may be called, for the sake of brevity, the bounty system in those foreign countries which manufacture sugar for exportation. In the course of his evidence before the Committee, Mr. James Duncan was asked if he could give any explanation of the fact that the growth of beetroot was practically confined to the Continent; and if no part of this country was adapted to the growth of beetroot. Mr. Duncan's reply was that it was adapted, but that the disadvantage of growing was owing to the bounty system, foreign sugar having a bounty which acted as a preventative to the growth of sugar in England, and which might be taken to be in the average 2*l.* a ton. In answer to further questions, Mr. Duncan stated that the bounty rendered it practically impossible to grow any beetroot in this country, though it could be done in the east of England of quite as good quality, if not better, than in France; but that, in face of the bounty, it was impossible.

Mr. George Martineau, giving evidence before the same Committee, said that he had given a very considerable amount of attention to the subject of the growth of beetroot in this country. One of the questions asked Mr. Martineau was as to the relative richness of roots grown in England as compared with foreign countries. In answer to this it was stated that Dr. Voelcker, the chemist to the

Royal Agricultural Society, found 12 per cent. of sugar in roots from Suffolk; 12½ and 13 per cent. in roots from Berkshire; 11½ per cent. in roots from Surrey; 10½ to 13¼ per cent. in roots from Yorkshire; and 10, 12, and 13, up to 15 per cent. in roots from Kilkenny. That was in 1870. Since then Mr. Martineau himself had taken a considerable amount of trouble in the matter, and had roots grown both in Lincolnshire and the Isle of Thanet; and as far as the latter were concerned had in his own laboratory extracted 15 per cent. of sugar; an amount of richness in which England, in his opinion, could certainly compete with France, where the average was not more than 10½ per cent.

My object, however, in reading this paper is not to repeat evidence given 10 years ago before a Select Parliamentary Committee, but to bring before you the results of my own experiments made last year on the farms of Mr. John Ennis, Springwood, Ballymitty, county Wexford, Ireland, and Mr. John Gibbons, Dunbabin farm, Wavertree, near Liverpool. For the purpose of these experiments four different kinds of beetroot seed were sent to me by Dr. C. Scheibler, the eminent sugar chemist of Berlin, and to all three gentlemen I herewith tender my best thanks for their kind co-operation. Before proceeding to give the results of my experiments I may mention that in Germany and Austria the roots have been grown for years under an artificial system which causes them to be produced of an excessive richness.

### YIELD PER CENT. OF WEIGHT OF BEETS.

	Per Cent.
1850-51 .....	6'66
1860-61 .....	8'62
1870-71 .....	8'61

1886-87 .....	11'87
1887-88 .....	13'08
1888-89 .....	11'96

In this respect Germany surpasses other countries, but from the smallness of the size of the roots there are not so many tons produced to the acre. The seeds I obtained from Dr. Scheibler were:—

1. Dippe's Zuckerreichste Elitezüchtung.
2. Gebrüder Dippe's Zuckerreiche Imperial Elitezüchtung.
3. Gebrüder Dippe's verbesserte Zuckerreiche rothköpfige Elitezüchtung.
4. Gebrüder Dippe's verbesserte Zuckerreiche Kl. Wanzelhohnen Elitezüchtung.

Of course you must not forget that, though I obtained the best seed procurable, both with reference to choice of soil and manure, I had to leave the necessary care of the plant to quite inexperienced hands. Possibly it may be the intention of some members of this Society to make experiments as I have done—experiments which I have already been asked to repeat by several Irish farmers. In such a case a hint or two about soil and manure may not be unacceptable. As to the first point, viz., the soil, it must be noted that very wet or swampy ground is quite unsuited for beet growing. What this requires is a loose clay containing lime, with a well-drained bottom. As to the second point, a very good artificial manure for beetroot is one containing one part of nitrogen to two parts of phosphoric acid as superphosphate. They spend as much as 5*l.* to 6*l.* per acre for artificial manure in Germany. The proportion wanted is about 200

to 300 lb. nitrate and from 400 to 600 lb. superphosphate, or 400 to 500 lb. Peru guano, and 200 to 300 lb. superphosphate per acre. The soil has to be ploughed up deeply—the deeper the better—unless the bottom ground is very different from the top. The usual plough goes from 7 in. to 9 in. deep, but it is necessary to go from 5 in. to 6 in. deeper. Of course my friends, the farmers in Ireland, and at Wavertree, near Liverpool, did not take these precautions, nor did they take any care to thin the plants as they grew up. The results obtained, therefore, are all the more surprising, as they show beyond the shadow of a doubt that beetroots can be grown in this country as rich in sugar as even in Germany,

where the richest are produced under an artificial system of duty.

Comparison with German roots was possible through the circumstance that Mr. F. O. Licht, of Magdeburg, publishes during the summer months a *resumé* of the results obtained by analysis in his laboratory of a quantity of freshly drawn beetroots. The day that he did this was always known to me, and on the same day, on several occasions, I had beetroots drawn from the earth both in Ireland and Wavertree, and had them analysed in my laboratory. You will find in the following tables the results of these experiments, which are positively surprising.

1 kilogramme (1000 grammes) equals about 2 lb. English weight.

I will now explain to you how I arrived at these results. The beetroots were drawn carefully out of the earth and brought to me without the loss of a single leaf. I then

washed and dried them quickly and weighed them with the leaves. This gave the first result. Then I cut the top and the root and weighed again, imitating the German manu-

## PLANT FOR DRYING BEETROOT SLICES

- A Endless Screw for feeding the Kiln with wet slices
- B Agitator for moving and turning the slices
- C Endless Screw for removing the dry slices
- D Air propellor to draw the Gases from the Furnace through the Kiln
- E Furnaces

The long arrows show the direction of the slices & of the gases.

facturers as they prepare their roots to go over the Custom house scales, having found by experience that the top and the root contain very little sugar. I imagine that Mr. F. O.

Licht gets at his figures for the weight of roots without leaves in the same way, as when I communicated with him on this point he found no fault with my mode of proceeding. The third operation was to get the juice. This has to be a very quick process, as chemical changes begin almost immediately, and therefore all tests must be applied as soon as the juice is squeezed out of the roots. I had, therefore, prepared four small boxes, each 1½ ft. long by 1 ft. broad, with punctured tops, resembling a large-sized bread-grater. Before each of these a boy knelt, grating one root at once; and when the full quantity had passed through, I pressed the mass in cloth of a very close-woven material in a filter-press, and the juice came out almost entirely clear, though dark in colour. As it is generally found that there is a great difference in strength of saccharine matter between the first and last juice coming out of the filter-press, I was very careful to press the cakes quite dry. The juice was then treated with sugar of lead and tannin, to clarify it, and then polarised. Another portion was gauged with Brix saccharometer, and some filtered through filter-paper before taking the specific gravity by weight. The results are all those of analysis of the juice, no allowance being made for the pulp, which is generally from 4 to 5 per cent. of the weight of the beetroot. I tested two lots of roots on the 17th October. No. 1 was 4.36 per cent., and No. 2, 4.41 per cent. of fibre. This result was obtained by extracting a weighed quantity of grated roots, at first with cold and later with boiling water, and drawing off both with a Scheibler felt filter and suction pump, and then drying the fibre in a tared filter. This fibre is of the greatest importance to farmers who grow the root for manufacturers, for, just as oilcake is a valuable by-product of seed-crushing, so there is not a better food for cattle than the beetroot fibre, which has from 10 to 12 per cent. of solids, which is as much as the beet generally used for feeding purposes, and it is usually mixed with hay, chaff, or maize. As food for cattle, therefore, beetroot is quite as valuable after the juice has been extracted as before.

As the sugar has, in latter years, been extracted from the beetroot by the diffusion process in many places, the residue would afterwards contain 11.99 per cent. of dry substance, with 4.84 per cent. of ash, which would fill and overload the stomachs of the cattle.

A great improvement has been achieved by drying the beetroot slices by a patent drying kiln, the construction of which will be easily understood by the accompanying drawing. This kiln is the result of a prize competition, and the inventors are Dr. Meyer and Mr. Buettner, and the apparatus has been constructed by Messrs. Langen and Hundhausen, in Grevenbroich, near Cologne.

With this apparatus they are able to dry 225,000 kilos. of beetroot per day, at a cost of 7.63 pf. per 100 kilos., or equal to almost 4d. per 100 lb. This dried residue contains 94.20 per cent. dried substance which gives 8.95 per cent. ash.

7½ to 8 ctr. beetroot slices dried this way give 1 ctr., and in spite of a certain taste of smoke and sulphur acquired from the fuel gases, and a small addition of lime, the cattle have taken kindly to the food, and, what is rather remarkable, do not seem to have required a larger quantity than usual. The advantages of this invention are, first, a healthy cattle food, and secondly, a saving in the cost of transit. The food can also be easily kept.

Another point to which I would draw your attention is the proportion of non-saccharine matter in the table of comparative results already given. This is simply the difference between the quantity indicated by the Brix saccharometer, which is supposed to show what quantity of sugar there is in the liquid, and the quantity shown by the polariscope which is real sugar. In the beetroots I examined I found a reaction by Fehling's solution, and I wrote to several experts on the Continent to ask them how they accounted for it. One of the replies, from Dr. O. Follenius, was to the effect that he thought the precipitate must have been yellow, and not red, and that would be caused by pectin, which is found in nearly every juice. Director C. Krüger, however, writes that he finds invert sugar in beetroots either grown in poor soils or not properly attended to. That may well have been so in my own case, as I have already told you the soil had not been specially prepared. The result to be arrived at from a consideration of all the circumstances is, really to discover how much per cent. of pure sugar it is possible to extract from 100 parts of the dry substance of the juice, and the higher this percentage is, of course, the better the beetroot. To calculate this, the saccharometer of Brix is used to show the dry substance of the juice, and then a calculation is made as to how much is sugar. Take, for instance, a juice that has 12 per cent. of sugar and shows 15 per cent. on the saccharometer. The result is 80 per cent. of sugar to 100 parts of dry substance. The results obtained by Dr. Follenius vary from 75.2 to 81.4 and 86.5 per cent. In my table you will find I got as much as 94.4 per cent.

As to the quantity I got per acre in my experimental cultivation, I am able to inform you that at Dunbabin farm, Wavertree, near Liverpool, we got 42 tons 19 cwt. per statute acre; and further, that the steward of Mr. Gibbons informed me Nos. 1, 2, and 3 seed gave an average crop, while No. 4 gave a very heavy crop. From my Irish friends I have not yet been able to obtain particulars as to quantity of crop per acre. Some people imagine that beetroot is an exhausting crop. On this point Mr. George Martineau gave very conclusive evidence before the Select Committee already mentioned as having been held in 1879. He quoted Mr. John Algernon Clarke, secretary to the Central Chamber of Agriculture, and Dr. Voelcker, chemist to the Royal Agricultural Society, to the effect that it is not an exhausting crop, and that it is one very favourable to the growth of wheat, the deep cultivation necessary to grow beetroot increasing the production per acre.

As a proof that the soil is improved by the cultivation of beetroot, and the extra tilling and manuring which such cultivation entails, I may mention the case of an estate called Groena, in the Dukedom of Anhalt, which comprises about 700 or 800 acres of fertile land. They did not plant any beetroot before 1837, and then up to 1853 only a few acres for a trial. In 1853, however, they began to plant about 150 acres every year, and in 1856 the results proved conclusively that they had got as much corn as they had formerly done when the whole area of the estate was devoted to its cultivation. On another estate, that of Ossnarsleben, near Bernburg, which comprised about 1,000 acres of fertile soil, they generally had a little more than half of it planted with corn. They found, after introducing the cultivation of beetroot, that they had an increase of about 2 per cent. in the corn crop. In France, in the Arrondissement of Valenciennes, not only was the corn crop increased by the introduction of beetroot, but they were able to feed

11,500 head of cattle instead of 700. The conclusion to which these facts point is obvious. Beetroot, so far from being an exhausting crop, positively enriches the soil if it is planted with a due regard to rotation. That is to say, if some years are allowed to elapse before the planting is repeated, it is not only a paying crop in itself, apart from the question of the value of its fibre as food for cattle, but that it positively increases the fertility of the ground for wheat or other cereal production.

Stable manure is very efficient, but ought not to be used on the land within, say, nine months of planting the beetroot seed. Lime is often of great advantage to the soil, but an addition of potassium salts has not proved remunerative.

The question naturally suggests itself:—How often can beetroot be planted to secure the advantages just mentioned? I have taken particular care to obtain trustworthy information on this point, and find the general opinion of those best informed to be once in six to eight years. For my own part, and in this I only express a personal opinion, I think that with the help of the advanced chemical knowledge of the present day, and by use of artificial manures, the period between the beetroot crops might be considerably shortened. The cause of the so-called "beetroot idleness" of the soil is a too frequent planting of beetroot on the same soil; this, however, has been attributed, not so much to the disappearance of the ingredients of the soil necessary to the beetroot, as to the enormous increase of "nematoids," small insects which are like diminutive eels, which, when young, are very agile, and penetrate the young roots, where they gradually thicken to such an extent that their moving power is lost. It is not alone the beetroot that these insects attack, but all cereals, especially oats, also cabbage, and many other vegetables. Their destruction occupies the minds of the agriculturists to such an extent that they have actually founded a special experimental station for this sole purpose. It seems that the most successful way of getting rid of them is to plant catch-plants, that is, such as the nematoids prefer, and then destroy the plants with the insects. A fungus—*Arthrobotrys oligospora*—which was found by Professor Zopf to destroy the nematoids has, however, only a chance where a good deal of water is present to sustain its existence.

I have seen it stated that 120 nematoids have been found in a small beetroot, and also that five times as much beetroot is grown on soil free from nematoids as on that infested with that pest. What I take to be the proper rotation of crops may be found in a pamphlet by Dr. C. J. Eisbein, who is the Professor of Agriculture at Heddesdorf, near Neuwed. This is as follows:—First year, beetroot fertilised with stable manure; second year, oats or barley; third year, clover and grass; fourth year, wheat; fifth year, peas, beans, or other leguminous plants or potatoes, fertilised with stable manure; and sixth year, rye. An alternative succession would be: First year, beetroot fertilised with stable manure; second year, barley or summer wheat; third year, clover or grass; fourth year, wheat; fifth year, potatoes; sixth year, oats; seventh year, leguminous plants, such as peas, beans, &c., fertilised with stable manure; and eighth year, rye. Beetroot may be planted again in the fifth year, but as to the advisability of doing this I am not in a position to say anything positive. As to the cost of production in relation to the profit, I will not trouble you with figures, but will merely remark that the profit is a little more than one-third of the outlay.\* No other crop, in fact, brings such a profit to the farmers on the Continent, except where they can plant tobacco or linseed.

The points to be borne in mind in connexion with what has been already said may be thus summarised:—

1. That sugar beetroot grows in any soil if it is rich in soluble mineral ingredients, and has nothing of pipe-clay or sand in its composition.
2. That sugar beetroot requires a soil with a deep foundation, and one that is very equal in its layers.
3. That the ground ought to be well drained, or to drain itself well.

4. That water is a necessity, but that water in excess is injurious to beetroot cultivation; and

5. That it is impossible to plant beetroot profitably oftener than every fourth year.

So far I have only spoken of the cultivation of beetroot from an agricultural point of view; but I have no doubt it will be equally interesting to those who regard the question as a purely financial one. On this point, I may be permitted to quote from a publication, which is, no doubt, known to most of you, viz.: "The Sugar Cane." In the issue for the last month I find the following:—

"Since the end of October the following results of German and other Continental sugar factories for the 1888-89 campaign have been announced. These are obtained, as usual, mainly from the Deutsche Zucker-industrie:—

#### Dividends Declared.

"Immendorf, 45 per cent.; Heilbroun, 15 per cent.; Bennigsen, 11 per cent., besides dividend to beet contractors.

#### Net Profits Shown.

Name of Place.	Capital.	Profits.	
	Marks.	Marks.	Per Cent.
Brühl .....	1,050,000	254,750	24
Neuwerk .....	1,500,000	162,514	11
Königsutter .....	240,000	191,063	81

Olfstein .....	621,000	77,162	12½
Tuezo .....	591,000	46,371	8

I have nothing more to add except to point out the immense advantages that would accrue to agriculturists both in England and Ireland from the cultivation of beetroot as a rotation crop. The evidence given before the Select Parliamentary Committee in 1879, especially by Mr. George Martineau, points clearly to the conclusion that but for the existence of foreign bounties beetroot for the manufacture of sugar might be profitably grown both in England and Ireland; profitably not only in the certainty of producing a valuable crop, but also in enriching and fertilising the soil, and at the same time providing the cheapest and most useful form of food for cattle. These points, let me remind you, are not mere matters of individual opinion, either of mine or anybody else. They are facts, the truth of which, as I have endeavoured to show, I have proved by my own experiments and experience; facts which have also been demonstrated in an even more conclusive way by the continental examples already quoted. That the cultivation of beetroot would be a good thing for England, and an especially good thing for Ireland, I hope that what has been already said has done something at least to prove.

#### DISCUSSION.

Dr. HURTER said that to anyone acquainted with the agriculture of this country or with the manufacture of sugar this paper would be very interesting. Dr. Schack-Sommer had opened a future both to Ireland and England for an alteration in their agricultural system. It would be of course a question for farmers and landlords to consider how far the material benefits to be derived from the alteration were borne out by Dr. Schack-Sommer's facts, but for them the great thing was to discuss the results of his experiments, and he should be glad to hear the discussion opened.

Mr. J. GIBBONS wished to know if Dr. Schack-Sommer could give them any idea as to the cost of growing a crop of beetroot in this country, and the value which the agriculturist might expect to get from it?

\* See table.

Mr. RHODES said he would like to know what kind of manure was used for growing the beets? He was not quite certain whether it was superphosphate, or nitre, or stable manure. He was under the impression that artificial manures were largely used on the Continent, and in consequence large percentages of sugar were obtained.

Mr. JOHN HAVES said the reader had mentioned that his two fields were not specially prepared, also that the results on the German estate appeared to increase from 1853 in the amount of yield per acre. He should like to know what crops had been previously grown on the fields at Wavertree and in Ireland. He understood that nine months were allowed to elapse before the crop came up. He would like to know at what time of the year these fields were treated. Another point was the using of a special kind of catch-plant to catch injurious insects. Were these catch-plants grown along with the crops, and did they come up together; if so did not they take up some of the food or nutriment from the soil which otherwise would have benefited the beets, or, was there some special way and time for laying down and rooting the catch-plants up, or were they ploughed up with the crops and picked out afterwards?

Dr. J. CAMPBELL BROWN said that Dr. Schack-Sommer's contribution was encouraging to agriculturists in view of the necessity for introducing some change—they knew not what—into the agricultural system which had hitherto prevailed. The difficulty of finding a market for beetroots remained and would remain for some time, but they hoped would disappear with the abolition of bounties. A farmer could not grow beetroot for the manufacture of sugar to be consumed on the premises. He must be in easy reach of the manufacturer on account of the speed at which decomposition sets in, and the manufacturer was not likely to set up his boilers, &c. in the present state of the sugar industry. But it was worth trying to grow beetroot for the feeding of cattle; and he was glad to see from the details that a good deal of the land in this country could be used for the growth of beet without any change in the system of agriculture, with the exception of the change of seed. A good deal of the land in Scotland was already grown on the six-year rotation system. Another question was that of climate. Did the beetroot require a warm genial climate, or would it grow in the raw cold climate of the east coast?

Mr. J. W. MACDONALD said beetroot-growing ought to be successful in this country, if the fiscal conditions on the Continent were not working against them. On looking over some figures about sugar that day he found that during the last four years (or since the 1885-86 crop) the cultivation of the beetroot had increased 57 per cent., whereas the cultivation of cane sugar had remained stationary or decreased 2 or 3 per cent.

Mr. COGHILL asked whether it would be cheaper to make sugar from beetroot grown in this country than from sugar cane imported from abroad?

Mr. BECK asked if it could be ascertained what the real profits to an agriculturist would be. He remembered a crisis some years ago when some special inquiries were made as to the cost of producing beetroot sugar, and he understood that the actual expense of making beet sugar from the root came to about 15s. a ton. They knew the percentage of sugar but they did not know the actual cost of beet sugar. They must not forget that the beet sugar had been grown on virgin soil in England as far as the beetroot was concerned. It was generally understood that the sugar beet took a great deal of power out of the ground. These things should be taken into consideration when comparing results.

Mr. E. CAREY said it was extremely refreshing to get for once out of alkali making into another branch of chemical manufacture. Dr. Schack-Sommer had given them an estimate of the profit that would accrue from the cultivation of beetroot. He (Mr. Carey) did not quite understand whether the profit was on beet grown here or in Germany. He also understood that the Germans had the advantage of a bounty which amounted to about 2*l.* per ton on the sugar. Of course that would handicap home growers very much.

He would be glad if Dr. Schack-Sommer could give them any idea as to what he would estimate the actual profit to be to an English agriculturist, supposing he could get results similar to those obtained at Wavertree and in Ireland?

Dr. HURTER asked what prospects there would be for a farmer finding a market for his beetroot in this country. Would the sugar manufacturers in this neighbourhood or elsewhere be prepared to erect plant for manufacturing sugar from beetroot?

Dr. SCHACK-SOMMER in replying said he should begin by answering the remarks of the last speaker. Of course there could be no prospect of the farmer getting rid of his beetroot until works were erected for the purpose of preparing the beetroot for sugar manufacture.

On the Continent, generally, where beetroot was grown, a certain number of farmers in each district clubbed together and built a factory, each farmer undertaking to deliver to the factory a certain weight of beetroot during the season. The factories were run on this principle, and after the owner's contract quantity was worked up they bought further quantities in the open market if they deemed it advisable, but by their system each factory was secured a minimum quantity at a stipulated price each season. As a rule the several factories were connected each with separate estates, and built in such situations as would afford the best facilities to the growers for delivering their produce.

With respect to the probable profit of beet growing which Mr. Carey and three other gentlemen referred to, Dr. Schack-Sommer said he had prepared the following tabular statement of the cost of planting and working of sugar beetroot, including delivery at the works, viz.: taking English measures and weights, which have been checked and found approximately correct by English farmers.

AMOUNT REALISED.	
The result per acre:—	£ s. d.
1. 33,079 lb. beetroot at 1 <i>s.</i> 1 <i>d.</i> per cwt. . .	15 19 10
2. 33 per cent. residue for feeding cattle = 11,371 lb. at 3½ <i>d.</i> per cwt. . . . .	1 10 2
3. 8,250 lb. leaves and roots at 3 <i>d.</i> per cwt. . .	0 18 6
	18 8 4
COST OF GROWING, &c.	
Topping stubble. . . . .	0 6 0
Twice harrowing. . . . .	0 3 0
Deep ploughing with four horses or steam .	1 2 0
Twice harrowing in spring. . . . .	0 2 0
Artificial manure. . . . .	2 10 0
Drilling, harrowing, drilling and rolling .	0 12 0
Hoeing and weeding. . . . .	0 2 0
33 lb. of beetroot seed at 3½ <i>d.</i> per lb. . . .	0 10 4
Horse-hoed or drilled three times. . . . .	0 6 0
Hoed by hand twice. . . . .	0 9 0
Thinning. . . . .	0 5 0
Banking the roots. . . . .	1 0 0
Sending roots to works. . . . .	1 16 0
To make the silos. . . . .	0 1 6
Interest on ground capital. . . . .	2 10 0
Ground dues and taxes. . . . .	0 18 0
	12 13 0
	£ s. d.
Amount realised per acre. . . . .	18 8 6
Expense of working (or all and every expense incurred). . . . .	12 13 0
Net profit per acre. . . . .	5 15 6

From this table it would be seen that the cost of production per acre was about 12*l.* 13*s.*, and as the produce brought in the market about 18*l.* 8*s.* 6*d.* there would be a profit of 5*l.* 15*s.* 6*d.* per acre for the grower.

He thought he had already anticipated Mr. Rhodes' question with regard to the fertilisers generally used very fully in the paper just read; but with respect to the two experimental fields, he was not then in a position to state exactly how they were manured. He could state, however, that no artificial fertilisers had been used but only ordinary farmyard manure. The crop raised at Wavertree the year before the beet was sown was oats.

The question was asked if the present year had not been an exceptionally good one for beetroot growing, to which Dr. Schaack-Sommer replied that his comparisons were made of course with roots grown during the same season, and therefore under similar climatic conditions, but speaking generally the yield of saccharine in 1889 was by no means abnormal nor equal to the highest of recent years, since the yield of saccharine in 1888 was over 13 per cent., whilst in 1889 the average was under 12 per cent. The weight of roots per acre, however, in 1889 was much heavier than in 1888; a circumstance which might be attributed to the extremely favourable conditions under which the beet was sown in 1889. Beet should be sown as early as possible in the month of April, while the ground contained a large amount of moisture.

Dr. Schaack-Sommer stated that the experimental seeds were procured for him by Professor Scheibler, who had selected them from the best source in Germany. They were of four different kinds, and were of course distinguished by different German names. He remembered when he was a student experimenting with beetroot in the laboratory of the Polytechnic School at Aix-la-Chapelle, and at that time his experiments were made with globular roots similar to the one exhibited. This kind of root had been abandoned in Germany for many years past, and the long carrot-shaped root had superseded it. Quite recently France had become alive to the superiority of the long root over the old-fashioned globular one, and for the past two years had been largely drawing her seed from German sources, with the result that the production of sugar in France had increased to an enormous extent.

With regard to the question of climate: climate of course affected the roots materially, but since the experimental roots had been grown in Wavertree and Ireland under the most unfavourable conditions, when the soil was not specially prepared for their growth, and the latter part of the season was cold and wet, and yet the yield from the roots compared most favourably with the best roots grown in Germany, it must be admitted that the experiment showed most indubitably that the climate of England and Ireland was highly favourable to the growth of sugar beets.

In reply to Mr. Hayes, Dr. Schaack-Sommer said that a "catch-plant" meant a plant to which the insect nematode would be attracted for the purpose of destroying them. For instance, after a crop of beetroot had been grown, and the ground was found to contain a number of these pests, a crop of catch-plants would be raised, the insects attracted to them, and then all destroyed together; then a crop, say of flax or any similar quick-ripening plant, might be sown, and after that was gathered a second crop of "catch-plants" raised the same season and so effectually clear the ground of the nematode, without losing the use of the ground for that season. I may just add before closing that a small factory, to do 50 tons per diem, including boilers, machinery, in fact, a complete plant (not including buildings), has been offered to me at 8,000*l*.

After Dr. Schaack-Sommer had replied, Dr. HURTER said that it was an important paper. He himself had seen such estates on the Continent as had been described. Dr. Schaack-Sommer had given them a number of financial statements of various companies; did those results include growing and manufacturing combined or the manufacture only?

Dr. SCHAACK-SOMMER: The manufacture only.

Dr. HURTER then said that about two years ago he had seen a sad picture. He had seen the ruins of what had once been a large establishment near Magdeburg. He inquired what had been carried on, and was told "sugar manufacture," and further that the works were not rebuilt because sugar did not pay. He was glad to hear of the dividends that had been lately paid, and with those figures in front of them he thought that somebody might be induced to erect works to procure a small market for beetroots. There was no doubt it would be a great assistance to the English and Irish farmers if they could make a profit per acre of 5*l*. 15*s*. 6*d*.

Meeting held at Victoria Hotel, Manchester, on  
Tuesday, 4th February 1890.

MR. IVAN LEVINSTEIN IN THE CHAIR.

### ON THE ESTIMATION OF ARSENIC ACID.

BY W. YOUNGER.

WHEN hydrochloric acid and potassium iodide are added to a solution of arsenic acid, iodine is liberated.

This takes place more readily on boiling, and if the boiling be continued for some time, the liberated iodine is eliminated, leaving a clear solution.

On examining this clear solution it is found that the arsenic acid has been reduced to arsenious acid, which on cooling and neutralising with sodium bicarbonate can then be titrated with standard iodine and the arsenic estimated.

The following experiments were made in order to ascertain if the arsenic acid was completely reduced.

A measured quantity of a standard solution of arsenious acid was oxidised by the addition of hypochlorite of lime solution, acidified with hydrochloric acid and boiled to expel free chlorine, potassium iodide added, boiled until the solution became clear, cooled, neutralised and titrated, the iodine taken up being equal to the arsenious acid employed.

Again, a measured quantity of a standard solution of arsenious acid was oxidised by titrating with standard iodine, hydrochloric acid added, boiled until the solution became clear, cooled, neutralised and titrated, the iodine taken up being equal to the arsenious acid employed.

The iodine vapour driven off on boiling in the last experiment was absorbed by passing it through two bottles, each bottle containing the same measured quantity of the standard solution of arsenious acid neutralised with sodium bicarbonate.

The contents of the two bottles were then mixed and titrated for the excess of arsenious acid, when it was found that the arsenious acid which had been oxidised by the iodine vapour driven off on boiling was exactly equal to the iodine employed in titrating before boiling, showing that all the iodine had been eliminated. The reaction is as follows:

As an excess of potassium iodide is always employed, it is generally found on cooling that a further slight liberation of iodine takes place, but this is prevented by the addition of a few cc. of glycerine, which in no way interferes with the working of the method. Nitric acid and nitrates if present

must be eliminated. The more hydrochloric acid present the sooner the liberated iodine is driven off on boiling. Results obtained by this method agree closely with results obtained by reducing with sulphurous acid. This method has been employed for estimating the arsenic acid in various substances, and has been found to give results closely agreeing with those obtained by the other well-known methods for estimating arsenic.

#### DISCUSSION.

DR. BAILEY said that he did not gather from Mr. Younger's remarks whether he claimed any originality for the method. As a matter of fact the distillation of oxides with hydrochloric acid and estimation by passing the chlorine evolved into a solution of potassium iodide had been long ago published by Bunsen and by Fresenius, whose methods only varied in detail. The method was an admirable one and capable of a high degree of accuracy when proper precautions were taken. If its application to the determination of arsenic acid were new, then he thought Mr. Younger deserved the thanks of the Society for bringing it before them, though he had used it himself regularly in the laboratory as a general method, and took it that as issued by Bunsen it was intended to apply to all peroxidized compounds.

#### ANALYSIS OF DEACON GASES.

BY W. YOUNGER.

THE following is a method which I have employed to ascertain the composition of the Deacon gases.

The chlorine, hydrochloric acid, moisture, air and excess of nitrogen are obtained from one aspiration, which is taken by means of the apparatus described in my paper in the Journal of the Society of Chemical Industry, VIII., 88—89, to which is added three small bottles, about 30 cc. capacity each, containing oil of vitriol, each of which is weighed separately before taking an aspiration.

In the accompanying Figure the gases are first drawn through the bottles containing the oil of vitriol for the purpose of absorbing the moisture, then through the tube containing arsenious acid, from which we obtain the chlorine and hydrochloric acid, while by means of the oxygen apparatus we obtain a reading of the oxygen in the gases contained in the graduated box, which gives us by calculation the air, the remainder of the gases in the box being taken as nitrogen.

After the aspiration is taken a chloride of calcium tube is coupled up to the oil of vitriol bottles and air drawn through all three in order to remove any chlorine which might be contained in the space above the oil of vitriol. The three bottles are then weighed, the increase in weight giving us the moisture. The chloride of calcium tube is for

the purpose of drying the air before passing it through the oil of vitriol.

The method for obtaining the chlorine and hydrochloric acid is described in my paper referred to above, while the air and excess of nitrogen are obtained by calculation after having taken a reading of the oxygen. It was necessary, however, to ascertain if any of the chlorine or hydrochloric acid was taken up by the oil of vitriol, for which purpose the total chlorine was estimated, the contents of the three bottles being found to contain about 0.03 of a grain.

The volume of the chlorine, hydrochloric acid, moisture and gases contained in the box are taken as the volume of the gases which have been drawn through, and from which the per cent. by volume of each is calculated.

An aspiration of the Deacon gases was taken which gave the following results:—

	Per Cent.
Air .....	80.50 by volume.
Chlorine .....	4.41 "
Hydrochloric acid .....	0.03 "
Moisture .....	2.46 "
Excess of nitrogen (by difference) ..	12.57 "

Meeting held in the College of Science, Thursday,  
February 6th, 1890.

MR. JOHN PATTINSON IN THE CHAIR

MR. SAVILLE SHAW exhibited a deposit of copper sulphate which had formed in the flue of a gas stove. The stove had a copper flue, and he explained the formation of the deposit, which, though greyish white, contained water nearly corresponding with that required by the formula  $\text{CuSO}_4 \cdot 5 \text{H}_2\text{O}$ , by supposing that the copper first oxidised, and that the copper oxide then brought about, in the way in which many metallic oxides are known to do, the combination of sulphur dioxide, from the combustion of sulphur in the gas, with oxygen; the trioxide so formed, or the acid formed from its reaction on the steam present, then forming copper sulphate with the copper oxide.

Mr. LOVIBOND instanced a similar case which had come under his knowledge, in which the bottom of a large brewing copper was destroyed and converted into copper sulphate through the use of a coal containing an unusually large amount of sulphur.

## PERSONAL RECOLLECTIONS OF THE "BACHET" PROCESS.

BY JOHN MORRISON, CHEMICAL ENGINEER, NEWCASTLE-ON-TYNE.

*Introductory.*—One of the earliest—if not the very earliest—of the various alkali processes carried out on the Tyne consisted in the decomposition of salt with litharge for the production of caustic soda—

This process was started at the Walker alkali works so far back as the year 1799, the salt being obtained from a brine shaft connected with the Walker colliery. The Walker works appears to have been the pioneer British alkali manufactory, and it is an interesting fact that the old hauling engine, with its massive oak beam and curious "sun and planet" motion—which had been erected in 1788 at the above pit by Messrs. Bolton and Watt—was not only a few years later saddled with the pumping of this brine, but was in active and useful work so recently as 10 or 12 years ago. Its steam was originally raised in (I believe cast iron) waggon boilers, and one or more of those of wrought iron which soon replaced the others, were, if I mistake not, in use as tanks up to the final dismantling of the Walker works.

How long the salt litharge process was continued at Walker's there seems to be no record to show; but it was probably abandoned prior to the adoption of the Leblanc process there in 1821. It is therefore not a little singular that at the very works, where half a century before the French process had probably ousted that of Lord Dundonald, a French gentleman was allowed to do his best to turn the tables on his own countryman, and to overthrow that process which the late Mr. William Gossage was wont to liken to a cat with nine lives, which none more than he had striven to destroy.

Up to the repeal of the salt tax in 1823 the Walker Alkali Company enjoyed the peculiar privilege of being allowed to make salt for soda manufacturing purposes free of duty. And with a litharge process so extremely imperfect it can only have been this fact, allied with what we should consider the then enormous price of soda, which at all enabled the manufacture to be carried to a remunerative issue.

In 1869 M. Bachet, a French banker and chemist, who had previously experimented at Channy, induced the Walker Alkali Company to erect experimental plant for the manufacture of caustic soda by his process, which differed from that of Lord Dundonald in the use of lime, and in the regeneration or revivifying of the lead for continuous use.

The plant was erected alongside what those who knew the Walker works 20 years ago will remember as the "hypo" house, where the Lo-sb hyposulphite soda process was carried on.

*Sodification.*—One part litharge, one part lime, half a part salt, and four parts water were ground together in an ordinary pan or mortar mill for about 20 minutes, by which time the creamy mass consisted of oxychloride and hydrated oxide of lead, undecomposed litharge, salt, and hydrate of lime, with caustic soda equal to 8 to 10 per cent. on the litharge employed instead of a theoretical 17.93 per cent. The use of lime, however, in this way was soon abandoned, for though it increased the solubility of the litharge, and caused a better decomposition, it possessed serious disadvantages. M. Bachet therefore subsequently treated two parts litharge and two parts salt with four parts water on the mill, which gave about the same total numerical result in soda as before, but with double quantities of lead and salt.

In practice the proportions were 2 cwt. litharge, 2 cwt. salt, and 4 cwt. water, these weights being adapted to the capacity of the plant in use. The mixture was ground on the mill from 20 to 30 minutes, by which time the whole had become white and thick. The large excess of water was requisite to bring the mass into a suitable consistency for pumping, and as soon as the mill operation was completed the charge was run off into a well, and thence forced into

filter-presses at a pressure of 100 lb. to 140 lb. per square inch. This probably was the earliest used of filter-presses for manufacturing purposes on the Tyne. The expressed liquors standing about 40° Tw. contained the soda together with a large quantity of salt, and PbO equal to about 1½ per cent. of the litharge used; and after precipitation with Na<sub>2</sub>S of the PbO as PbS, the clear portion was run into open pans and boiled down. The salt was rapidly as it collected was fished out and thrown on to perforated iron draining benches suspended over the pans, the steam from the boiling brine being intended to percolate these fishings, and to carry back to the pans their last traces of caustic soda. But it was an extremely imperfect—if not wholly useless—arrangement, and a hydro-extractor would probably have proved infinitely more efficient.

When as much salt as was possible had been fished from the liquors, they were run into a caustic pot to be finished in the usual manner. But it was found very difficult with the appliances and methods in use to completely separate the caustic soda from the salt. For whereas the first brine fishings contained only about 25 per cent. NaHO, the proportion steadily increased as the evaporation advanced, so that the later fishings would test as much as 15 per cent. to 16 per cent. NaHO.

Some of this excess was removed by lixiviation with fresh liquors, but the practical results were by no means as satisfactory as could have been desired.

**Regeneration.**—The magma from the filter-presses was returned to the mill, ground up with a little fresh water, and repressed to extract last traces of soda. The clear liquor standing about 18° Tw. was added to that from the first pressing; and the pressed cakes, which then weighed 25 per cent. to 30 per cent. more than the original litharge, were once more ground up with a little water and pumped into a conical iron regenerating vessel. Here a quantity of lime water equal to about 10 times the weight of the original litharge was added, the whole agitated for 30 to 40 minutes, and allowed to settle, the clear liquor being run off to vats.

Then the precipitate at the bottom of the regenerator was treated with a second 10 parts lime water, boiled for 15 minutes with constant agitation, and the clear liquor added to the first in the vats. During this operation the precipitate began to lose its white colour, and after another repetition with a third 10 parts water the clear liquor gradually became bright green. Finally a third boiling with only five parts lime water was given, and then, when after settling, the supernatant liquors were run off, the mass at the bottom of the vessel was found to be completely transformed into litharge again, and ready for a fresh operation on the mill.

The whole amount of water therefore used was equal to 35 times the weight of the original litharge employed. The first agitation with cold water extracted the last traces of salt, and (as calcium chloride) a portion of the chlorine combined with the lead. And the remaining washings with hot water removed the rest of the chlorine, besides dehydrating the hydrated oxide of lead. The decomposition of the PbCl formed of necessity the first reaction, for the presence of this PbCl prevented the last one taking place. And it was absolutely necessary to run off the clear liquors without delay, as a reverting reaction rapidly ensued.

The large volume of lime water employed necessarily carried away much lead in solution. An amount indeed equivalent to about one-tenth of the weight of litharge originally employed. It was necessary, therefore, to recover this by passing through the regeneration liquors in the vats a current of carbonic acid gas until a slip of blue litmus paper became red. The settled liquors having then been run off, the PbCO<sub>3</sub> precipitate was collected and boiled for half an hour in water to which the requisite quantity of lime was added for the formation of CaCO<sub>3</sub> and PbO. This reaction readily took place, but the difficulty then was to separate the lead from the chalk. And the only plan which seemed to offer was to maintain a gentle agitation just sufficient to keep the milky white CaCO<sub>3</sub> in suspension until siphoned gradually off. When this operation was carefully performed, about 50 per cent. of the PbO originally precipitated was found at the bottom of the vessel nearly free from CaCO<sub>3</sub>. The siphoned liquors containing the CaCO<sub>3</sub>

and the remainder of the PbO were then treated with sufficient hot water to dissolve the latter. And finally the CaCO<sub>3</sub> was settled out as worthless, and the clear liquor was removed for process use. It was, in fact, of the utmost importance to preserve this, for the CO<sub>2</sub> present in Tyne water would, if not got rid of in this way, have seriously affected the results in a process requiring such immense quantities of water for its completion.

I ought to mention that at first the PbCO<sub>3</sub> precipitates were regenerated in a specially constructed reverberatory furnace, but the method was so obviously objectionable that it was speedily supplanted.

The advantages of M. Bachet's newer method over the original "lime system" were as follows:—

1. Increased facility of regeneration. For whereas 100 parts water were necessitated by the old plan, 35 parts only of lime water sufficed in the amended one. In fact the excess of lime first used really retarded the regeneration, and the reduced quantity of water and lime in the new system considerably diminished the total quantity of lead dissolved even with the double quantity of litharge used. For the effect of the additional lime itself, apart from the increased water, was to augment the PbO solubility.

In the amended process the liquors from the first pressing contained about 25 per cent. PbO, and those from the second pressing about 10 per cent. PbO, which represented about one-third the quantity present in the lime process liquors.

2. The composition of the magma in the improved process was so comparatively constant that testings of each pressing were not absolutely necessary. This was decidedly not the case after three or four operations when working with lime.

3. An increased regenerative rapidity resulted in the new method from the more rapid settlement of the lead from each regenerating water.

I here subjoin the results of a series of operations which I find in my note-book, though in all probability they did not represent average work.

#### 1st operation:—

2 cwt. fresh litharge.  
2 " salt.  
4 " water.

Produce = 8·29 lb. NaHO = 3·7 per cent. on PbO.

Magma from presses = 288 lb.

Soda brine = 608 lb. containing 25 per cent.

PbO = 1½ per cent. on PbO.

Magma regenerated with 30 parts water to which 12 lb. CaO were added.

#### 2nd operation:—

Regenerated litharge.  
2 cwt. salt.  
4 " water.

Produce = 5·64 lb. NaHO and 214 lb. magma.

#### 3rd operation:—

Twice regenerated litharge with NaCl and H<sub>2</sub>O as before.

Produce = 5·83 lb. NaHO and 214 lb. magma.

#### 4th operation:—

Thrice regenerated litharge with NaCl and H<sub>2</sub>O as before.

Produce = 6·09 lb. NaHO and 215 lb. magma.

These four operations therefore required no less than about 13 tons water for regeneration, and 16 cwt. for sodification (less only the quantity returned to process from the PbCO<sub>3</sub> precipitating vats), against a production of 25·85 lb. NaHO.

**Objections.**—Hence, however promising the Bachet process might have been in theory, it must be evident that there were immense difficulties to overcome in practice. There were great volumes of water and large masses of solid materials to be moved about in order to secure a comparatively insignificant output, and where you had perforce to chuck in expensive litharge by the hundredweight, in order to extract with difficulty NaHO by (one might almost say) the pound, it becomes evident that stragulative commercial losses were almost inevitable. But M. Bachet himself was always hopeful and indomitably persevering. And yet while

I by no means think that the two years' experiments at Walker nearly exhausted the subject, they made it to my mind perfectly clear that the salt litharge decomposition would require to be much more complete, that the losses in irrecoverable, and in depreciated lead would have to be much less serious; that the enormous consumption of water would have to be greatly reduced; and that the separation of the  $\text{NaHO}$  from the brine and the fished salt would have to be rendered much less difficult before any practical man could reasonably anticipate an approaching dawn of success.

M. Bachel maintained that the new soda resulting from the reaction,  $\text{PbO} + \text{Na}_2\text{S} + \text{H}_2\text{O} = \text{PbS} + 2\text{NaHO}$ , would defray the cost of the  $\text{Na}_2\text{S}$  used to precipitate the lead from the pressed liquors. But the great depreciation in lead value involved by the sale of the  $\text{PbS}$  to the lead smelters, at one-third or one-fourth the cost of the original litharge, far more than counterbalanced this, and was indeed a rather discouraging drawback.

It was also hoped that the pressed soda liquors might be repeatedly employed on the mill with the regenerated litharge; but it was found that they caused no reaction without an addition of salt nearly equal to that employed at first.

In the same way it was also discovered that when fished salt was substituted for fresh salt, a considerably reduced chemical action ensued. That in fact whatever soda remained in the fished salt remained not simply dormant but in some occult way retarded the desired decomposition, and that hence, the same total amount only of  $\text{NaHO}$  was obtained from it as would have resulted from the use of a corresponding amount of fresh salt wholly free from  $\text{NaHO}$ . Then there was the great difficulty in separating the  $\text{NaHO}$  from the fished salt, to overcome which the conversion of the  $\text{NaHO}$  in the brine liquors into  $\text{NaHCO}_3$ , and recovery by precipitation from the more soluble salt was attempted. But so far as tried the plan was not a success.

Numbers of temperate and intemperate estimates as to manufacturing costs were from time to time during the course of the experiments painfully elaborated, but no one series of calculations, so far as practical accuracy was concerned, had probably any right to be regarded as more demonstrably reliable than another.

I have several among my stray memoranda, and may just give one as an example:—

Rough preliminary data for estimating manufacturing costs:—

Basis = batch of 5 cwt. litharge, 5 cwt. salt, and 10 cwt. water } With a production of 4 per cent.  $\text{NaHO}$  or litharge used.

Four per cent.  $\text{NaHO}$  or litharge = 22.4 lb.  $\text{NaHO}$  per batch.

Mixed liquors from 1st and 2nd pressing = 15 cwt. or	Lb.	Lb.
Less total water on magma	1,580	
	194	1,486

Add water in  $\text{Na}_2\text{S}$  precipitating solution = say 14

Total water to be evaporated from soda brine per batch = say 1,500  
per 22.4 lb. pure  $\text{NaHO}$  or 32 lb. 70 per cent. of caustic soda = 49 tons per 1 ton 70 per cent. caustic soda.

Salt per batch of soda liquor..... Lb. 569

Less salt retained in 70 per cent. caustic soda..... Lb. 3.25

Less  $\text{NaCl}$  per batch transformed into  $\text{NaHO}$  and  $\text{PbCl}$ ..... 42.2 45.5

Salt per batch to be fished out..... = say 514.5  
= say, 16 tons per 1 ton 70 per cent. caustic soda.  
Say, 1 part  $\text{CaO}$  soluble in 700 parts  $\text{H}_2\text{O}$ .

Line water for regenerating pressed magma = 35 times weight of original litharge, or 19,600 lb. per batch = 28 lb.  $\text{CaO}$  per batch or 17.5 cwt. per 1 ton 70 per cent. caustic soda.

Also 6.8 lb.  $\text{CaO}$  or 6,860 lb. (say, 7,000 lb.) lime water will be necessary for regenerating  $\text{PbCO}_3 = 4\frac{1}{2}$  cwt.  $\text{CaO}$  per 1 ton 70 per cent. caustic soda.

Total  $\text{CaO}$  per 1 ton 70 per cent. caustic soda = say, 22 cwt.

The calculation of this lime should nearly produce sufficient  $\text{CO}_2$  for precipitating the  $\text{PbO}$  in regenerating waters; or  $\text{CO}_2$  produced from coke would give, say, 7.7 lb.  $\text{CO}_2$  from 4.7 lb. coke (at 45 per cent.) to convert the 39.2 lb.  $\text{PbO}$  into 46.9 lb.  $\text{PbCO}_3$  or say 3 cwt. per 1 ton 70 per cent.  $\text{NaHO}$ .

Depreciation of lead in soda liquors. If latter contain 1 lb.  $\text{PbO}$  per 10 lb.  $\text{NaHO}$ , there will be 22.4 lb.  $\text{PbO}$  or 240 lb.  $\text{PbS}$  per ton pure  $\text{NaHO} = 165$  lb.  $\text{PbS}$  per 1 ton 70 per cent. caustic soda, which at, say, 15d. depreciatory loss per ton = 22s. 6d. per ton 70 per cent. caustic soda.

From this and a considerable quantity of minor data, I calculated on October 24th, 1871, the Bachel manufacturing costs per 1 ton 70 per cent. caustic soda to be as follows: It will be evident, however, that the estimate is extremely incomplete and speculative. For instance, I have presumed upon the cost of water to be wholly represented by the cost of pumping from the river, to say nothing of its storage, &c. Also the cost of finishing or fusing the caustic soda, and some other items, are probably very wide of the mark. Nothing also is down for oxidising sulphides or caustic liquors. Still, it formed an honest attempt at reasonable accuracy at the time named, the presumption being (somewhat unfairly, perhaps) that certain difficulties then unresolved were really practically overcome, or would be so with larger and more perfectly equipped plant. And the figures given having been reduced from those yielded by an assumed weekly output of 50 tons 70 per cent. caustic soda, were thought to offer a much better chance towards arriving at practical accuracy than any which might be directly based upon a single ton.

#### COSTS OF 1 TON 70 PER CENT. "BACHEL" CAUSTIC SODA REDUCED FROM FIGURES OBTAINED FROM A 50-TON WEEKLY ESTIMATE.

	£ s. d.	£ s. d.
Coals .....	3 11 8½	
Coke .....	0 1 2½	
Burnt lime .....	0 18 2½	4 11 1½
Depreciation on lead as sulphide.....	1 2 6	
Further loss of lead throughout process, say.....	1 0 0	
Loss of salt .....	1 3 1½	3 5 7½
Labour:		
Engines and boilers.....	0 3 10½	
Mills and presses .....	2 14 8½	
Oxychloride regenerators .....	0 9 7	
$\text{PbCO}_3$ regenerators .....	0 2 10½	
Soda liquors (precipitation of $\text{PbS}$ , &c. &c.).....	0 0 11½	
Soda liquors (evaporation, firing, fishing, &c. &c.) .....	1 13 1	
Preparing lime water .....	0 0 11½	
Finishing and packing caustic soda.	0 1 5	
Repairs and sundries .....	0 2 1½	
Caustic drums .....	1 0 0	6 9 10
Management, &c. ....	0 3 7	
Interest on capital and depreciation..	1 18 5½	2 2 0½
Total manufacturing costs .....		16 8 7½

I do not recollect at this distance of time the market value of 70 per cent. caustic soda in 1871, but in all probability it did not exceed 12l. to 15l. per ton.

MR. G. BEILBY IN THE CHAIR.

## AN ACCOUNT OF THE MANUFACTURE OF PHOSPHORUS.—PART I.

BY J. B. READMAN, D.Sc., F.R.S.E., F.C.S.

THERE are few more interesting elementary substances than phosphorus. Its history is associated with the later alchemists, and the uses to which it is now applied are numerous and important.

It appears to be nearly certain that phosphorus was first discovered by Brand or Brandt, an alchemist belonging to Hamburg, more than two centuries ago. He prepared the element from evaporated urine, which contains but a small amount of phosphoric acid.\*

The process was at first kept secret, but was afterwards sold, and then the method of preparing phosphorus began to be found out, for it appears that the Hon. Robert Boyle contributed a paper on phosphorus to the Royal Society in 1680. He obtained it, as Brand did, by heating a mixture of evaporated urine and sand in an earthenware retort, condensing the distillate.

About a century later Gahn discovered the existence of phosphate of lime in bones, and in a few years after we learn that the Swedish chemist Scheele described in detail a process by which he prepared phosphorus from bone-ash.

He warmed the bone ash with dilute nitric acid and then precipitated the soluble lime with sulphuric acid. He then

evaporated the liquid from which the gypsum had been separated to a thick syrup and distilled the dried residue with charcoal.

This roundabout process was first simplified by Nicolas and Pelletier, and afterwards improved upon by Fourcroy and Vauquelin. Those chemists treated the ground bone-ash direct with sulphuric acid, first determining the exact amount of acid required for its complete decomposition. About this time phosphorus was proved by Lavoisier to be an elementary body.

Bone-ash has been used for the preparation of phosphorus from the days of Scheele till quite within recent years. Now, however, native mineral phosphates of lime containing quite as much phosphorus as bone-ash contains have taken the place of the latter in the estimation of the phosphorus manufacturer, owing no doubt to the lower price at which it can be obtained.

When selecting a phosphate of lime for the production of phosphorus by the ordinary method care is taken to obtain one which contains a high percentage of phosphorus, and at the same time a minimum amount of iron and alumina. We shall see the reason of this when the details of the process are further described.

Pure bone-ash conforms to this description to a marked degree, as we may see by the following analysis:—

	Per Cent.
Phosphoric acid .....	39.55
Lime .....	52.46
Magnesia .....	1.02
Ferrie oxide .....	0.17
Silica .....	0.51
Carbonic acid, alkalis, fluorine, &c. .	4.43
Water .....	1.86
	100.00

Among the mineral phosphates that are met with in the market suitable for the manufacture of phosphorus those known as Canadian, Spanish, Somme, Sombbrero, and Norwegian apatite may be taken as typical examples. The following are analyses of these:—

	Canadian.	Spanish.	Somme.	Sombbrero.
Phosphoric acid ( $P_2O_5$ ) .	37.51	33.38	35.29	34.78
Lime .....	51.18	47.16	50.22	37.97
Carbonic acid' .....	..	4.10	2.97	1.46
Oxide of iron .....	..	2.59	2.46	..
Alumina .....	8.38	0.89		
Fluorine .....	..	..	..	..
Magnesia .....	..	..	5.20	0.46
Sulphide of iron .....	..	..	..	..
Sulphuric acid .....	..	0.57	..	0.45
Alkaline salts .....	..	..	..	..
Chlorine .....	..	..	..	..
Insoluble, &c. ....	2.85	..	5.61	2.84
Total water and organic matter .....	0.08	7.30	1.40	12.36
Undetermined .....	..	4.01	..	10.08
	100.00	100.00	99.15	100.00

Another mineral phosphate found native in one of the Leeward Islands in the West Indies and known by the name of "Redonda" phosphate—from the small island from whence it is derived—has been proposed as a source of phosphorus.\*

\* The island of Redonda is situated about 25 miles to the south-west of Antigua, 26° 6' lat., 61° 35' long., and is under British protection. Its length is estimated at one mile, its breadth at a third of a mile, and its height at 1,000 ft. The coast is rocky and only affords a single landing place, situated at the south-west, not far from the foot of a ravine in a rock. (See this Journal, 1889, 63.)

\* The usual amount of phosphoric acid in urine is .21 per cent. = .691 per cent. of phosphorus.

This mineral is not a phosphate of lime—like those just mentioned—it consists of phosphate of alumina and iron without any lime, and has the following percentage composition:—

	Per Cent.
Phosphoric acid ( $P_2O_5$ ) .....	39.23
Alumina .....	23.48
Peroxide of iron .....	10.60
Silica and insoluble .....	5.85
Combined water and organic matter ..	17.20
Moisture .....	3.66
	<hr/> 100.02

Equal to phosphorus 17.12 per cent.

Large quantities of Redonda have been shipped to this country since the deposits were discovered about 25 years ago, amounting, it is said, to 20,000 tons. The mineral was guaranteed to contain 35 per cent. of anhydrous phosphoric acid, and has been the subject of numerous investigations and patents, some of which are of an exceedingly ingenious nature.

For example, Spence\* dissolved the ground mineral in sulphuric acid, and to the solution he added sulphate of ammonia or sulphate of potash, and crystallised out the alum which resulted, leaving phosphoric acid in the mother-liquors. Townsend roasted the powdered phosphate after intimately mixing it with soda ash. The residue he dissolved in water, and on evaporation and crystallisation obtained tribasic phosphate of soda ( $Na_3PO_4 + 12 H_2O$ ), leaving aluminate of soda in the mother-liquors. The phosphate of soda was then dissolved in water and the phosphoric acid precipitated by milk of lime.

This process yielded a remarkably pure precipitated phosphate of lime.

Carbonic acid was next passed through the mother-liquors (of aluminate of soda), by which gelatinous alumina was precipitated and carbonate of soda left in solution ready on evaporation to be used over again.

The specimen of Redonda which lies on the table is taken at random from a large cargo imported some years ago into this country. It contains 35 per cent. of anhydrous phosphoric acid, and loses about 25 per cent. in weight when heated to dull redness, the loss being organic matter, combined water and moisture. The roasted sample contains a higher percentage of phosphorus than is contained in the purest phosphate of lime obtainable in commerce. Notwithstanding this, and the low price at which this mineral can be obtained, none of the processes proposed for the removal of the phosphoric acid appears to have been adopted.

In describing the manufacture of phosphorus as at present carried on, I purpose dividing it into several stages under the following heads:—

1. The preparation of phosphoric acid from phosphate of lime and sulphuric acid, with description of the apparatus employed.

\* Spence patented two processes, the first in 1870, which was incomplete, and was perfected by a second patent in 1873. The first idea was to dissolve the phosphate of alumina in sulphuric acid, and to the solution add ammonia or potash to form an alum; then crystallise. To the mother-liquid add ammoniacal gas water, iron, and any residue of alumina were precipitated, and the clear liquor was boiled down and dried to a state fit for manure; the amendment of this patent was that after the iron, &c. had been thrown down by the ammoniacal gas water and phosphate of ammonia obtained, pure ammonia was added to the monophosphate, and a tribasic phosphate of ammonia was formed.

The second process consisted in mixing the mineral phosphate with sulphate of soda (salt cake), coal, and a little oxide of iron, and heating these together until decomposition took place; then lixiviating out the phosphate of soda that is formed; to this solution caustic lime is added, phosphate of lime is precipitated, and caustic soda remains in the liquor; this is boiled down in the usual way; the precipitated phosphate is either used as it is, or it is converted into superphosphate.

Spence was so confident of the success of this process that he decided to erect plant on a large scale, and to alter the arrangement of his works. He was too sanguine, and his conclusions were at least premature, for after incurring heavy expenses the process had to be abandoned, and large quantities of the mineral were thrown on his hands.—"Life of Peter Spence, of Manchester, from Chem. Trade Jour., January 14th, 1890."

2. The concentration of the phosphoric acid, together with an account of the mixture of the acid with carbonaceous matter.
3. Phosphorus retorts and furnaces, with description of the distillation and condensation.
4. Refining and packing.

1. *The Preparation of Phosphoric Acid, &c.*—This is prepared from one or other of the mineral phosphates of lime, which is ground to a fine powder and then decomposed with chamber sulphuric acid of 1.55 sp. gr. The decomposition is effected in large wooden tuns made of pitch pine or other suitable wood, and provided with agitators also made of wood. Open steam is blown in during the operation. Sufficient sulphuric acid is added to convert all the lime present in the phosphate of lime into sulphate of lime.

After the expiry of some hours, during which the contents of the tuns are continually agitated, the emulsion is run off to large wooden filters lined with lead and provided with false bottoms or having ashes in layers of various sizes spread over the floor of the filters.

Here the hydrated sulphate of lime is separated from the solution of phosphoric acid, which passes through the filter as a bright and clear sherry-coloured fluid.

At first the phosphoric acid runs from the filters at 1.17 sp. gr., but gradually gets reduced by careful washing to 1.01 sp. gr.

Special precautions are observed to avoid cracks on the surface of the gypsum contained in the filters, the formation of which would afford too ready an outlet for the washing water.

Whenever the effluent from the filters reaches sp. gr. 1.01 the washing is stopped, and the hydrated sulphate of lime is piled up in the centre of the filters to drain, and finally it is thrown out.

This waste product usually contains about 62 per cent. of water, and when this is expelled by heat what is known as phosphatic gypsum is obtained having the following composition:—

#### Phosphatic Gypsum.

	Per Cent.
Sulphate of lime (anhydrous) .....	71.14
Phosphate of lime .....	6.56
Silicious matter .....	12.10
Oxide of iron, alumina, organic matter ..	5.55
Combined water and moisture .....	4.65
	<hr/> 100.06

2. *The Concentration of the Phosphoric Acid, and Apparatus employed.*—The strong phosphoric acid liquor flowing from the gypsum filters is blown by one of the acid-resisting steam elevators, "blow jacks," to stock tanks, and from there it is run by gravitation to the evaporators, which are circular tanks made of iron or wood, lined with thick lead, and heated by means of lead coils and high-pressure steam. Each evaporator is provided with an agitator, which is kept in motion during the evaporation.

Sulphate of lime, which is slightly soluble in the acid liquors, is deposited as the evaporation advances, and so great does this deposit become that filtration or decantation is necessary before the acid attains the degree of concentration required. If no agitation is employed during the concentration the gypsum firmly attaches itself to the coils, forming around them a thick coating, which must be removed by chipping.

The precipitated gypsum is thrown on a filter and washed in the manner previously described. When the clear acid liquor becomes concentrated to sp. gr. 1.4 or 1.5, the evaporation is stopped, and any deposited gypsum again separated.

The strong solution of phosphoric acid should now contain a mere trace of lime. Any iron, alumina, or magnesia present in the original phosphate of lime is dissolved to a considerable extent by the sulphuric acid treatment, and appears in this acid liquor.

A specimen of the concentrated acid is lying on the table containing 62.19 per cent. of  $P_2O_5$ , and no lime.

The strong syrupy acid is now mixed with carbonaceous matter, such as wood charcoal or coke, in coarse powder,

to the extent of about 25 per cent.; it is then carefully desiccated either in iron pots or in a muffle furnace so as to expel all the moisture, sulphurous acid, and hydrocarbons, and afterwards it is carefully stored away in air-tight iron boxes ready to be used in the distillation.

**3. Phosphorus Retorts and Furnaces with description of the Distillation and Condensation.**—The distillation is carried out in small bottle-shaped retorts made of the best weathered and prepared Stourbridge fire-clay; these retorts or pipes are about 3 ft. long by 11 in. external diameter—the clay being about 1 in. thick.

The retorts are placed in a furnace something like a Belgian zinc furnace in construction, but having only two tiers of retorts, each row being placed back to back with their narrow mouths projecting an inch or so through the brickwork. There are 28 retorts in one furnace, that is to say—taking one side of the furnace and considering it for a moment—there are in the first tier seven retorts and directly above these there are another seven, making 14 retorts which, as explained, project slightly through the side of the furnace. The other side of the furnace is similarly equipped.

The mouths of the retorts are connected to the condensers by 2-in. malleable iron or copper pipes which are luted with clay joints both to the retort and to the condenser.

Hot water is used in the condensing trough, so that whenever the phosphorus is condensed it fuses and runs down by gravitation to the lower end and may then be lifted out conveniently by a ladle.

Each retort holds between 20 and 30 pounds weight of phosphorus mixture and yields up the phosphorus existing in the free uncombined phosphoric acid in about 15 hours.

Whenever the distillation is completed the 2-in. pipes are disconnected from the retorts and the residue is rapidly withdrawn and the bench of retorts again recharged, the heat being steadily maintained.

Should a retort be cracked or fused either during the distillation or at charging, any phosphorus mixture it may contain is withdrawn, the dampers are closed and the retort removed from the furnace; a new retort, heated in an adjoining kiln to the required temperature, is substituted and all proceeds as before.

The crude phosphorus thus obtained is dark mahogany-brown in colour, as may be observed in the large specimen of this substance placed before you. It contains a good deal of impurity.

**4. Refining and Packing.**—The crude phosphorus is fused under water in a lead-lined circular tank heated by lead coils for high-pressure steam or steam jacketed. As much water as can safely be decanted off the surface of the crude phosphorus is removed and about 4 per cent. of bichromate of potash (on the weight of the crude phosphorus), is added in solution. An agitator with which the vessel is provided is set in motion and is continued in motion during the refining. After stirring for half an hour with the solution of bichrome about the same weight of oil of vitriol is added; in this way chromic acid is formed which oxidises the lower oxides of phosphorus and leaves the element pure and nearly colourless.

Another method of refining, and one more suitable under certain conditions, is to redistil the crude phosphorus in an iron retort. The phosphorus distils over rapidly and at a comparatively low temperature. A combination of these two methods is in some ways desirable.

The refined phosphorus is next moulded into "wedges" or "sticks." The "wedges" are made by melting the phosphorus and transferring it into circular tin dishes, 10 in. diameter by 4 in. deep, and when filled a star-shaped mould is introduced into each, which divides the circle into 10 wedge-shaped pieces, suitable for packing into tin cases. After this cold water is introduced, which soon solidifies the phosphorus and admits of its easy removal.

#### DISCUSSION.

Dr. DOBBIN asked how the inaccuracy of the text-book statement regarding the manufacture of phosphorus (which was so very explicit) was to be accounted for. Had the

statement no real foundation in fact, and who was the author of it? Was the process which Dr. Readman had described the one carried out by the very few phosphorus manufacturers in the country?

The CHAIRMAN asked if it was an essential feature of the process that the retorts should be as small as had been stated? He thought it would have added further to the interest of the paper if some idea of the cost had been given.

Dr. READMAN, in reply, said that it was not to the interest of manufacturers to correct mis-statements in text-books. With reference to the smallness of the retorts, in his experiments he commenced with a gas retort, but found it to be an entire failure, and he was of opinion that it was impossible to make a retort to stand the necessary heat more than 4 ft. long. As to the cost, he did not think it would be of interest to give it, but perhaps in his concluding paper he would say something in that connexion.

#### MOISTURE IN PAPER PULP.

BY G. H. GEMMELL, F.C.S., F.I.C.

STRAW and wood pulp as imported into this country from Germany and Norway—in bales of from 2 to 4 cwt. each—contains a high percentage of water, varying from 40 to 60 per cent., but the price of the material is usually based on the amount of air-dried substance present. The amount of moisture, however, in an air-dried pulp varies within considerable limits, according as the fibre is derived from wood or straw, and also according as it is prepared by mechanical means only, or by the soda, bisulphite, or other chemical process. It is also known that variations of temperature and humidity of the atmosphere causes a considerable change in this figure. In the paper trade there is no fixed standard adopted, some pulp manufacturers selling their material on the basis that it contains 12 per cent. of moisture when air-dry, others only 10 per cent., while many paper-makers affirm that 8 to 9 per cent. should be the utmost limit allowable; nor is there a uniform method adopted for calculating the weight of air-dried substance from the absolutely dry pulp, hence discrepancies and disputes often arise between buyer and seller. The paper-maker who tests his own pulp usually adds 10 or 12 per cent., as the case may be, to the percentage of absolutely dry pulp found, and this method of calculation is apparently acquiesced in by some of the manufacturers of pulp, but it is obviously incorrect. A sample of pulp containing, say, 60 per cent. of moisture and 40 per cent. of absolutely dry pulp, would by this method be said to contain 44 per cent. of air-dry material, but the correct method of stating is that if 90 of absolutely dry pulp becomes 100 air-dried, what will 40 absolutely dry become, this gives 44·44 per cent. as the correct figure. I have made a few experiments with a view of ascertaining what should be the average amount of moisture allowed for in an air-dried pulp, and though incomplete, think the results may be of interest to members of this Society. A sample of straw pulp containing 60 per cent. of water was allowed to remain exposed to the atmosphere, at the ordinary temperature of the laboratory, for 14 days, being turned over daily to expose fresh surfaces. A weighed quantity was then dried in a water oven, till constant in weight. 421 grms. of this air-dried pulp became 377 grms. of absolutely dry pulp, or a loss of 44 grms., which is equivalent to 11·67 per cent. of moisture, calculated from the dry pulp. Another sample of this same pulp, first made absolutely dry, was also exposed during the same 14 days, and was again re-dried. 1,102 grms. of the air-dried pulp became 1,017 grms. of absolutely dry, a loss of 85 grms., equivalent to 8·35 per cent. of moisture

Here we find that two samples of the same pulp, one wet and the other dry, do not become equal in the percentage of moisture after 14 days' exposure, but differ by 3.32 per cent., though at the end of the first seven days there was no perceptible difference to the touch in the wetness of the samples.

A similar trial was made with a sample of wood pulp containing 55 per cent. of moisture, and side by side with some of the same pulp previously made absolutely dry. At the end of five days there was no perceptible difference in the wetness of each sample, but they were kept exposed for five days more and a portion of each was then dried. The previously wet pulp by that time contained 13.6 per cent. of water, the previously dry pulp 10.6 per cent., a difference of 3 per cent. The remaining portions of these samples were exposed for a further seven days and then dried; the wet pulp then contained 12.2 per cent. moisture, and the dry pulp 10.4 per cent., a difference of 1.8 per cent. The moisture in the previously dry pulp thus remained practically constant while that of the wet sample more nearly approached that of the dried sample, and it was apparently only a question of being exposed for a sufficient length of time for the percentage of water to be equal in each. The weather during these trials was generally damp and wet, hence the results are probably above rather than below the average, and therefore 10 per cent. of moisture does not appear to be an unreasonable allowance to make for air dried pulp. In connection with this matter it may be of interest to note that the "Scotsman" and "Dispatch" newspapers contained when air dried 9.4 and 9.1 per cent. of moisture respectively, and two different makes of note paper 7.7 and 7.4 per cent. To obtain an average sample of the pulp for analysis is of course of the utmost importance, but owing to the nature of the material and the method of packing in bales is one of no little difficulty. 100 tons of pulp represent 1,000 bales, and to open 10 per cent. of these would be out of the question, and I have generally found that the paper-maker and seller agree that 10 to 15 bales in all are sufficient to open. The sample should also be taken as early as possible after the arrival of the consignment, and it might be advisable in some cases to weigh each bale before opening to remove the sample, though it is scarcely within the province of the chemist to do so, and from the figure thus obtained the paper-maker can calculate the amount of moisture originally in the bale. Thus suppose 10 bales invoiced at 3 cwt. each were weighed before taking the sample and were found to average 2 cwt. 3 qrs. or a total of 1 ton 7 cwt. 2 qrs., this is a total loss in weight of 2 cwt. 2 qrs. If on testing the sample drawn from these bales 55 per cent. of moisture is found, then the actual weight of dry pulp in the 10 bales would be  $\frac{45}{100}$  of 1 ton 7 cwt. 2 qrs. = 12 cwt. 1 qr. 14 lb., as the bales originally weighed 30 cwt. the amount of dry pulp then present was—

$$\frac{12 \text{ cwt. } 1 \text{ qr. } 14 \text{ lb.} \times 100}{30 \text{ cwt.}} = 41.08 \text{ per cent.}$$

It has been suggested that to obtain a sample a hollow steel punch should be driven through the bale, and the portion thus obtained transferred at once to a weighing bottle. Another method is to take a piece of the pulp from each sheet in the bale, but I think both these methods open to objection. The most satisfactory method is to open the bale to the middle, a sharp chisel being the best tool to use. Three strips 2 or 3 inches wide are then taken in every case right across the bale, from end to end. The first strip is taken from the external portion of the bale three or four layers deep, the second strip midway between the external and middle portions, and the third strip from the middle. 30 to 40 strips in all are thus taken. These are rapidly torn to pieces of about 1 in. square and thoroughly mixed, and from this a sample weighing 2 to 3 lb. removed to the laboratory for the analysis. The sample should be securely tied in oiled paper—this being more satisfactory than bottles—the loss of moisture not being more than a fraction of a per cent. In testing for moisture, weigh out 4,000 to 5,000 grains in a large beaker, dry for 22 hours in a water bath at 100° C. and weigh, and then again for a further two hours or till the weight is constant.

## DISCUSSION.

MR. IRVINE asked if the wood or straw pulp was sold on an absolutely dry basis, or as containing such a percentage of moisture as these fibrous materials attract to themselves? The reason he asked that question was, because he once knew a very serious lawsuit that arose over a somewhat similar case.

THE CHAIRMAN asked how far in a matter of that kind atmospheric moisture made a difference? He noticed that certain kinds of writing paper took the ink differently on a dry day from a wet day.

MR. GEMMELL said, in reply to Mr. Irvine, that the paper was always sold as containing a certain percentage of moisture. That basis varied. The Germans said that the paper absorbed 12 per cent., others said only 10 per cent., while paper-makers generally allowed 7, 8, or 9 per cent., at the most. As to the Chairman's question, the kind of weather made little difference in the amount of moisture absorbed, perhaps not more than 1 per cent.

## Journal and Patent\* Literature.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

#### PATENTS.

#### Improvements in Refrigerating and Freezing Apparatus.

H. Puplett and J. L. Rigg, London. Eng. Pat. 507, January 11, 1889. 8d.

This invention relates to improvements in that class of refrigerating apparatus in which a liquid is heated in one vessel, the gas or vapour being driven off into a second vessel, in which it liquefies by accumulated pressure and subsequent cooling. The first-named vessel being then cooled, and the pressure thereby reduced, the liquefied gas returns in the gaseous form, to assume which, it abstracts heat from the liquid surrounding the second vessel, being itself absorbed again by the mother-liquor remaining from the previous operation in the first vessel.

According to the inventors, an apparatus of this kind constructed in the ordinary way is liable to the danger of explosion from over-heating, to avoid which and to raise the general efficiency, they, instead of employing a liquid direct, use gas or vapour from an anhydrous liquid which readily gasifies, such as carbonic anhydride, ammonia, or ether. They next introduce into the first vessel, as an absorbent, any substance which does not evaporate, but possesses the property of readily absorbing the gas or vapour, such as charcoal, calcined clay or calcium chloride. They also prefer to make the first vessel in duplicate for working alternately,

\* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d. ....	3d.
Above 8d., and not exceeding 1s. 6d. ....	1d.
" 1s. 6d., " " 2s. 4d. ....	1½d.
" 2s. 4d., " " 3s. 4d. ....	2d.

one being heated whilst the other is cooled. The specification is accompanied with one sheet of drawings on which two varieties of the improved apparatus are illustrated.—B.

*Improved Means for Preventing Ignition, and Retarding Combustion.* A. V. Newton, London. From A. Nobel, Paris, France. Eng. Pat. 568, January 11, 1889. 8d.

THE main object of this invention is to prevent the flame arising from the ignition of blasting charges in mines from communicating itself to the surrounding atmosphere and thereby igniting any fire-damp or combustible matters that may be suspended therein. It can also be applied to the protection of buildings from fire. To effect this, the air of the mine or building is saturated with water by means of a fine spray, thus rendering it incapable of supporting combustion, though mixed with volatile combustible liquids such as benzine (petroleum spirit), ether or bisulphide of carbon.

"Provided the dispersion is fine enough, no fire can be fed by atmospheric air holding its own weight of water in suspension."—E. S.

*Improvements in the Method of and Means for Concentrating or Evaporating and Distilling Solutions for the Production of Dyes and other Bodies.* J. Frost, Moldgreen. Eng. Pat. 1803, February 1, 1889. 8d.

THE improvements consist in the methods of heating the solutions and chemicals, and of promoting rapid concentration and evaporation, in order to economise time and labour, to prevent waste and to lessen the amount of heat required. A vertical coil formed of pipes of any suitable material has thin inclined plates fixed along each side of the pipes. The coil being heated by the passage of steam through it, the solution to be concentrated is allowed to flow on to the top of the first pipe, from thence on to those below in succession, and becoming gradually heated is "thrown off the pipes on to the thin plates, in the form of spray." The solution is thereby rapidly concentrated and ultimately falls into a receiver. Some modifications of the apparatus are shown on the two sheets of drawings attached to the specification.—E. S.

*Improved Means and Apparatus for Softening and Purifying Water, and for the Removal and Prevention of Incrustation in Steam and other Boilers.* E. Harrison, London. Eng. Pat. 1847, February 1, 1889. 8d.

A NUMBER of perforated central plates of copper and zinc of any suitable shape are arranged alternately, and placed between larger outer plates of perforated zinc or meshed wire, which are kept apart by studs, the whole apparatus being threaded on a central spindle provided with a nut and thumbscrew at the lower end, and a hooked head at the upper end, for readier transportation. The outer plates are cut radially, and are turned up in a fan-shape, the lower tips of the arms "forming feet upon which the apparatus stands upon an insulated base in the boiler," the whole, when in use, "inducing and establishing galvanic attractive action under the influence, and by the agency of the heat of the boiling water; and the incrustation of fur, instead of being deposited on the boiler plates, as usual, is deposited upon the meshed wire, &c., from which it is readily removed."—E. S.

*Improvements in or Pertaining to Funnels or Reservoirs for Liquids.* H. G. Payne, London. Eng. Pat. 1891, February 2, 1889. 6d.

THE lower part of the conical head of the funnel is closed with a diaphragm, in which a hole is left, closed by a valve.

The opening and closing of the valve is governed by a float, which is suspended in the narrow neck of the funnel, and

is acted upon by the liquid rising in the lower vessel as it is being filled, thereby preventing an overflow.—B.

*Separating Liquids of two different Densities.* Sir B. Samuelson, Bart., Banbury. Eng. Pat. 3016, February 20, 1889. 6d.

THIS invention relates to certain improvements in apparatus for separating liquids of different densities, such as milk and cream, and has reference more particularly to the position of the inlet and the outlet openings for the liquids, and to their adjustment. For details, the specification and drawing must be consulted.—B.

*Improvements relating to Distillation, and Apparatus therefor.* B. Hoff, Jaroslau, Austria. Eng. Pat. 3468, February 26, 1889. 8d.

THIS invention relates to the distillation or refining of liquids which are composed of fluids of various boiling points, the object being to obtain the purified product or products as a result of one distillation only, by means of inexpensive apparatus and without the use of cooling water.

The improvements consist in exposing to a succession of condensing surfaces of regulated areas the mixed vapours rising from a liquid under treatment, whereby, according to the principle upon which the improvements are based, the gases are condensed in the order of the boiling points of the resulting liquids, those possessing higher boiling points being condensed first, and those with the lowest last. The apparatus may consist of a number of upright cylindrical vessels conveniently grouped together, each vessel provided with a division or false bottom, on which the condensing material is placed, such as pebbles, shingle, or other silicious matter. Pipes connect the vessels to convey the vapours from the lower part of one to the upper part of the succeeding vessel, suitable valves being provided for drawing off the condensed liquor from each. The following examples are given of the extent of condensing surface required in the treatment of various liquors:—

To separate ethyl ether in a pure state (boiling point, 35.5° C. or 96° F.) from other vapours formed during its manufacture, which vapours generally consist of alcohol (boiling point, 78.4° C. or 173° F.) and steam (100° C.), 900 square metres (9,690 sq. ft.) of condensing surface are required when dealing with a volume of 100 cub. m. (3,532 cub. ft.) of the mixed vapours.

To separate pure wood spirit from water and the empyreumatic oils, 1,200 sq. m. (12,916 sq. ft.) are needed. The same for chloroform.

To separate benzene from toluene and its other attendant gases, 3,000 sq. m. (32,292 sq. ft.).

For aqueous sulphuric acid only 400 sq. m. (4,305 sq. ft.).

To separate petroleum vapour from steam, 14 sq. m. (150 sq. ft.) are requisite when obtaining a distillate having a boiling point of 150° to 170° C. (302° to 338° F.) and 0.82 sp. gr.—B.

*A "Boiler Composition," for the Cleansing and Prevention of Incrustation of Steam Boilers.* J. Parsons, Newnham. Eng. Pat. 8583, May 23, 1889. 4d.

This is a mixture of coal-tar, various oils, soda-ash, soap and tallow, which requires to be painted over the inside of the boiler.

It is claimed that the composition will in time fill up the pores of the plates, and so render the inside of the boiler "smooth and glass-like," and prevent oxidation and incrustation.—D. A. S.

*Improvements in Apparatus for Determining the Quantity of Moisture in Steam.* G. H. Barnes, Reading, Mass., U.S.A. Eng. Pat. 10,521, June 28, 1889. 8d.

In this invention the determination of the total quantity of moisture contained in steam is carried out in two stages. In the first, the steam drawn from the main is made to deposit part of its moisture by gravitation in a vessel which is provided with water-gauge and draw-off cock, whence the resulting deposit is run off and weighed. In the second stage the partially dried steam passes a thermometer previous to reaching a small orifice through which it issues into the atmosphere, whilst a second thermometer records the temperature of the issuing steam. As all the moisture remaining in the steam after the first deposition is evaporated during expansion, the issuing steam becomes superheated or attains a higher temperature than that due only to its density under atmospheric pressure. The difference of temperature recorded in this manner gives a measure of the amount of moisture left in the steam before expansion, and this added to the weight of water withdrawn from the depositing chamber determines the percentage of moisture as compared with the whole weight of steam passed through the apparatus. Numerical examples are given in the specification.—B.

*Improvements in Furnaces or Kilns for Burning Bone-Black.* A. Weber, New York, U.S.A. Eng. Pat. 12,070, July 30, 1889. 1s. 3d.

The furnace or kiln is constructed on the regenerative system and heated by means of gas generated in a separate furnace. The raw bones are fed automatically by gravity from stationary hoppers to the vertical retorts of the kiln. The bone-black retorts are oval-shaped, made of refractory material, and provided at their upper end with cast-iron mouthpieces which are closed by covers communicating by means of cast-iron sockets with feed pipes which are also connected with bottom openings of hoppers placed above the kiln. To the kiln placed vertically below the retorts are attached air-tight coolers fitted with dampers at their lower end, which are operated automatically by suitable mechanism so as to discharge the bone-black in small quantities at suitable intervals of time, a corresponding quantity of raw bones being fed through the feed pipes into the upper ends of the retorts. The gases of distillation in the retorts are drawn off by means of an exhaustor, and after the liquid products of distillation have been separated therefrom, the gas is reconnected to the furnace and utilised in heating the retorts. The tar obtained is also burned in the furnace and adds to the economic results obtained in working the kiln.

—F. S.

*Improvements in Apparatus for Condensing Vapours and Cooling Gases or Liquids.* J. Popper, Vienna, Austria. Eng. Pat. 16,763, October 23, 1889. 6d.

The improvements "relate to air condensers and cooling apparatus, in which air is used as the cooling medium, and the liquid to be cooled does not come into direct contact with the cooling air itself, but is contained in a closed vessel." For the mode in which this is effected the drawings accompanying the specification must be consulted.—E. S.

*An Improved Instrument for Sampling or Gauging the Depth of Liquids in Tanks, Vats, or other Vessels.* E. E. Horley and F. Sedgley, London. Eng. Pat. 17,275, October 31, 1889. 8d.

The instrument consists of a glass tube open at both ends, and having a valve adapted to close against the lower end. This valve hangs below the tube whilst it is descending through the liquid, but on reaching the bottom of the tank the progress of the valve is stopped; the glass tube, suitably weighted, continues its descent until it comes in contact with the valve, when a spring-catch retains the latter against the lower end of the tube. The instrument can then be withdrawn, when the nature and depth of the lower stratum of fluid, however small, being visible through the glass tube, can be measured by a scale.—E. S.

## II.—FUEL, GAS, AND LIGHT.

*Wery's Apparatus for Heating Retort Furnaces.* L. Brémond. *Journal des Usines à Gaz*, 1889, 153; *Proc. Inst. Civil Eng.* 99, 49.

THE cost of fuel for heating retort furnaces is a most important expense in the manufacture of gas. Various recuperative furnaces for utilising the waste heat are known, likewise the non-conducting coverings of Le Treust and others, besides other means that have been proposed for economising the fuel. It costs the Paris Gas Company 14½d. for fuel for producing 35,300 cub. ft. of gas, while the cost to many other companies is double that amount, and, in small works, the cost rises to as much as 9s. 7d. per 35,300 cub. ft. These differences may be partly due to variations in the price of the fuel; the coke being, in some places, valued at the selling price, while others calculate it at a uniform and conventional rate. However this may be, considerable variations do exist in the quantity of fuel used for heating the furnaces, even in the best managed works of similar sizes, and the differences become enormous if small works are compared with large ones. It is therefore desirable to find a simple and inexpensive means for economising fuel, applicable to all gasworks, and Wery's apparatus fulfils these conditions, effecting a saving of from 15 to 20 per cent. in the fuel.

On behalf of the Mechanical Arts Committee of the "Société d'Encouragement," Mr. Pillet has reported on Wery's smoke-consuming chimney, the principles of which are simply to mix a certain quantity of relatively cold air with the furnace gases in the chimney; this is effected by the application of the principle of Giffard's injector; the air mixes with the hot gases in the chimney, passing through a circular orifice, reduced in section as much as possible, and proportional to the chimney. The current of cold air surrounds the furnace gases in motion, mixes with them, lowers their temperature and diminishes the velocity of the draught. Without considering the theory of the principle, or determining whether similar results could be obtained by carefully regulating the dimensions of the exit orifice, Mr. Pillet found, from two carefully-made experiments, that the Wery process was efficacious both for smoke-consumption and economy of fuel. He experimented with a 12-h.p. portable engine and a tubular boiler without return flues or artificial draught. The consumption of smoke was perfect,

and the economy of fuel, with Wery's apparatus, for an equal amount of work, and for the same quantity of water evaporated, amounted to 23 per cent.

Other trials were made by Mr. De Bange, General Director of the old Cail manufactory at Paris, with 20-h.p. and 80-h.p. engines, and with puddling furnace and generator furnaces. Decided economy of fuel was found and also a sensible reduction in the time required for getting up steam. With the steam boilers the saving was about 20 per cent., and with the puddling furnace, in addition to the economy of fuel, the quality of the iron was superior to that obtained before using the apparatus. Mr. De Bange also made a trial to determine the quantity of water evaporated per pound of coal, with and without the apparatus, and found that the steam produced per pound of coal was increased by 28 per cent. by the apparatus.

Trials were also made at Denain by Mr. Jubeau with a puddling furnace on two steel ingots, each weighing about 4 tons, in two similar furnaces, the one with, and the other without the apparatus; these showed an economy of fuel of 16.79 per cent. in favour of the apparatus.

Other trials have also been made by Mr. J. Gaudry in the shops of the Compagnie Transatlantique, at Penhoet, which gave 10.2 to 10.7 lb. of water evaporated per pound of coal with the apparatus as compared with 7.8 lb. of water per pound of coal without it.

As regards gasworks, the Wery apparatus produces a similar effect to that of Le Treust, which creates an intermittent draught in the chimney and drives the products of combustion back into the furnace when the register is closed. With the Wery chimney, vacuum and pressure are alternately seen, according to the condition of the fuel. No machinery or steam is required. It can be fixed to existing chimneys, but the most convenient plan is to construct a brick foundation and place the apparatus on it, surrounded by a sheet-iron chimney. An apparatus and chimney of a total height of 30 ft., and the chimney  $11\frac{1}{4}$  in. diameter, was substituted for a brick chimney 62 ft. high and  $35\frac{1}{2}$  in. diameter; so that such large chimneys are not required, and the flames are not seen escaping at the top. At the small gasworks where it is in use, and where the dampers have to be closed each evening until the following morning, the heat is maintained and the furnace regains its ordinary temperature in half the usual time; there was also an economy of 16 per cent. in the fuel in the month of March, with intermittent working; but it will be easily understood that in winter, when the furnace is working regularly day and night, the economy would be considerably greater, the more so because the apparatus gives better results when the outer temperature is low. This was proved at the same works during a 12 days' trial in November last, when the saving in fuel was 28 per cent., as compared with the corresponding period of the preceding year. The Wery apparatus is of very simple construction, and requires only occasional cleaning when coal or tar are used for fuel. It is destined to become generally used in gasworks, as it will effect considerable economies which have not hitherto been realised by any other system.

*Storage of Petroleum used as an Illuminant for Prussian Lighthouses.* Zeits. für Bauwesen, 1889, 397, and Proc. Inst. Civil Eng. 99, 51.

PETROLEUM is almost exclusively used as the illuminant for lighthouses on the Prussian seaboard, and a description of the various special store-tanks is given, and their efficiency is considered; the principal ends kept in view being the avoidance of waste by leakage, and in drawing supplies, and maintaining a low temperature.

The tanks are of wrought iron, and generally of a size sufficient for storing a year's supply. Their shape is cylindrical, the larger ones of 3 ft. 3 in. diameter, 5 ft. high, constructed of  $\frac{5}{16}$ -in. to  $\frac{3}{16}$ -in. plates for the sides,  $\frac{1}{2}$ -in. to  $\frac{3}{4}$ -in. for the cover, and  $\frac{3}{8}$ -in. to  $\frac{1}{2}$ -in. for the base, that which is of the main importance being an efficient closing of the joints.

They are made in four different manners, viz.: 1st, of single plates with double-riveted joints; 2nd, of the same,

but with caulked joints; 3rd, of the same, but with brazed joints; and, 4th, with a double skin, forming a water-jacket, with single riveting and caulked or brazed joints. The third-mentioned method is that found to be the most efficient, although expensive. One objection to the water-jacketed tanks is that in frosty weather the water has to be let off.

Diagrams are given showing the various forms of tanks, and of the special brickwork cellars in which they are placed, these being generally isolated from the other buildings. The tanks are fitted with glass gauges, and are filled by a hose passed through a trap in the roof of the cellar.

For comparison with the present improved method of storage, a return is given relating to various lighthouse stations under the old system, when the oil was drawn direct from the casks, and varied from 5.4 to 13.7 per cent.

A tabular statement is given of the number of tanks and their form of construction at each of the 17 lighthouse stations, the names of the makers, the cost, cubical content, cost per litre, and percentage of loss per annum now and formerly, the greatest loss quoted being reduced from 13.7 to 1.01 per cent.

Particulars are also given of the cost of construction of the cellars at six stations.

#### PATENTS.

*Improved Methods of producing Combustible Gases and in Apparatus therefor.* B. H. Thwaite, Liverpool. Eng. Pat. 16,970, November 22, 1888. 8d.

THE gas distilled from coal in the ordinary way is caused to pass through a second retort containing incandescent coke, the residue from an earlier distillation. When gas has nearly ceased to be evolved, valves are reversed, and superheated steam is driven through both retorts, entering the second one first. Any heavy hydrocarbons that may have deposited in this second retort "are broken up, and re-arranged" by the superheated steam, which, both here and in the first retort, is itself decomposed, yielding a considerable quantity of water-gas before the temperature falls below the point required for this operation. The gas produced after the admission of the superheated steam may either be mixed with the ordinary coal-gas first obtained, or employed separately. In place of coke broken brick may be used in the second retort.—A. R. D.

*Improvements in Apparatus for the Manufacture of Gas for Illuminating and other Purposes, which Improvements also render said Apparatus suitable for other Uses.* F. J. Jones, Leek, and L. Alexander, London. Eng. Pat. 17,613, December 3, 1888. 8d.

THE process consists essentially in effecting the distillation of the coal or other material at a comparatively low temperature (so that the benzene and other hydrocarbons of high illuminating power may not be decomposed) by causing the gaseous products of combustion from a furnace to pass through a stratum of coal, so that the said products will be mixed with the gas and tarry vapours and other hydrocarbons which distil off, and in then superheating this mixture of gases and vapours, whereby the volatile constituents are converted into a rich permanent gas whilst the excess of carbon is deposited.

The gas, instead of being generated under the pressure necessary to force it through the hydraulic main and being allowed to cool down immediately after leaving the retort as in the ordinary retort system, passes freely or under exhaustion from the distilling chamber (no hydraulic main being used), and is then immediately superheated, "the gas passing from the superheater directly to the purifiers" (unless it is required to be cooled down, which may advantageously be done by passing the gas through a regenerator) after which it is ready for consumption.

The improved apparatus wherein this process is carried into practical effect is described, and drawings forming part of the specification are given, which it is necessary to consult in order to clearly understand.—F. S.

*Improvements in Apparatus for Utilising Liquid Hydrocarbon for Lighting and Heating Purposes.* F. B. Hill, London. Eng. Pat., 17,869, December 6, 1888. 11d.

Liquid hydrocarbon is forced by compressed air from a reservoir into an annular vaporising chamber which surrounds, or is surrounded by, an annular passage for the vapour from the chamber to the burner. This passage surrounds, or is surrounded by, another passage for the supply of atmospheric air to the burner. The chimney either extends upwards through the centre of vaporising chamber, or surrounds the air passage, thus enclosing the whole arrangement. The vapour and air currents travelling downwards meet under the vaporising chamber to form an annular flame, having a downward direction, and curling either outwards or inwards, according to the disposition of the chimney. It will be seen that the heated products of combustion, passing away up the chimney, may be made to heat the air required to support combustion, and to assist in the vaporising of the hydrocarbon, though this is chiefly effected by the action of the flame on the lower surface of the vaporising chamber.

—A. R. D.

*Improvements in Regenerative Kilns.* E. Brook and J. J. Brook, Huddersfield. Eng. Pat. 18,451, December 18, 1888. 11d.

The kilns are preferably built in sets of not less than four. Overhead run a main gas passage and a hot air flue. The upper part of each kiln constitutes a combustion chamber, and below this the goods to be fired are placed upon a floor perforated to allow connexion either with the chimney draught or with the outer air. The connexions and damper arrangements are such that while, say No. 1 kiln is being heated by the internal combustion of gas with hot air supplied from the overhead passages, the products of combustion escape through the perforated floor, and may be made to heat other kilns on their passage to the chimney. When the firing of No. 1 is finished, air is drawn in through the perforated bottom, and, passing through the kiln, reaches the hot air flue above in a highly heated state. It is now available either for supporting combustion in a kiln in course of firing, or for drying and heating goods in another kiln.

—A. R. D.

*Improvements in the Production of Water-Gas and in obtaining Hydrogen, Carbonic Oxide, or Carbonic Acid, each separately therefrom, also obtaining certain By-products.* C. F. Claus, London. Eng. Pat. 50, January 1, 1889. 8d.

Though "water-gas" produced according to any method may be treated by this process for the separate recovery of its constituent gases, the patentee prefers to prepare it by passing superheated steam through a layer of fuel, the relative proportions of carbonic oxide, carbonic acid, hydrogen and ammonia produced depending upon the depth of the layer of fuel and upon the temperature of the steam. By this means a continuous current of "water-gas" can be obtained without the use of an air-blast and the previous ignition of the fuel.

The gases, after cooling, are scrubbed or washed with ammonia in order to recover the carbonic acid (ammonia being also retained) as sequeicarbonate of ammonium, and then passed over oxide of iron after previously heating the gases to a temperature (100—500 C.) at which oxide of iron is reduced by hydrogen but not by carbonic oxide. The carbonic oxide passes on to a gasholder, while the hydrogen unites with the oxygen and leaves spongy metallic iron from which hydrogen is regenerated by means of superheated steam. Suitable apparatus is described for the continuous working of the process; for instance, the carbonic acid is driven off in a heating apparatus from its solution in ammonia, the ammonia being returned to the scrubbers for repeated use, while the carbonic acid, after passing through a tower containing sulphuric acid to retain any ammonia, and through an oxide of iron purifier, is led to the gasholder. The process may be used in conjunction with the ammonia-soda process, the free ammonia produced in this

latter process being used for the removal of the carbonic acid from "water-gas," while the sequeicarbonate of ammonium can be utilised in the ammonia-soda process.—O. H.

*Improvements in Apparatus for Carburetting Gas.* J. D. Hall, Liverpool. Eng. Pat. 387, January 9, 1889. 8d.

A COPPER box is divided into compartments by a number of perforated copper slides, or partitions. Between the copper slides are also arranged a series of flannel curtains or diaphragms, the lower portions of which dip in any suitable hydrocarbon contained in the box. The gas to be carburetted traverses the apparatus from end to end, and in passing through the flannel becomes charged with the vapour of the hydrocarbon, this latter being constantly replenished from below by capillary attraction. At both inlet and outlet are situated catch-boxes to obviate any difficulties that might be caused by condensation.—A. R. D.

*An Improved Composition of Artificial or Block Fuel.* C. H. Mowll, Dover. Eng. Pat. 1806, February 1, 1889. 4d.

BRUQUETTES, which are stated to be less friable and of more value as a combustible than ordinary briquettes, are made by compressing a mixture of slack or small coal with pulverised peat. Cinders, ashes or calcined coal and an adhesive or agglomerative substance, such as pitch, may be added if desired, the mixture being moistened or slightly heated before compression.—O. H.

*Improvements in or relating to the Generation of Gases known as Water-Gas, Siemens' Gas, and Producer-Gas, and in Apparatus connected therewith.* J. von Langer and L. Cooper, Leeds. Eng. Pat. 7252, May 1, 1889. 11d.

This invention relates to improved forms of producers or gas generators, to the admission of air to the producer, and to improved valves and their arrangements, and mode of actuating valves in groups.

A is the producer, B the fire-bars, C the fire-cleaning doors, D the hearth, E the ash doors, F is an outlet for

Fig. 1.

water-gas, and G a corresponding outlet for Siemens or producer-gas. At the top of the producer (in some cases) an outlet H is provided to carry off the products of combustion when lighting up or cleaning the fire, and is closed by a suitable valve. Air is admitted to the fuel in the producer through a series of openings I I, at different planes in the circumference, controlled by suitable valves J J. A special or main supply of the air blast is indicated at K, entering beneath the green fuel and controlled by a suitable valve K<sup>1</sup> placed in the blast pipe, the producer-gas generated finding an outlet through the openings G G at the base. When the air is shut off and the steam is turned on at L, water-gas is likewise generated in passing downwards and finds an outlet at openings F F (not shown) at opposite points to G G.

In this figure the main blast enters the bottom of the producer at K and passes upward through H, controlled by valve H<sup>1</sup>, while air is also admitted at points I I as in Fig. 1.

Fig. 2.

Steam is admitted at L, and the water-gas outlet is at F. The fuel is fed through hopper M, dropping upon an inclined shelf, from which it falls gradually into the body of the producer.

The specification further contains drawings of a producer adapted to turn in a circular direction upon an axial bearing, and in doing so to open or close the inlets for steam and air, and outlets for the gases. Also a producer mounted upon the ram of a hydraulic press, and adapted to move up and down in a vertical line.

A suitable controlling valve and box for admitting air at several points to the producer, and a water-gas valve, are shown in the drawings by detailed sections.—F. S.

*Improvements in Heating Boilers by Gaseous Fuel.* O. Inray, London. From E. R. Ware, Chicago, U.S.A. Eng. Pat. 15,043, September 24, 1889. 8d.

THIS consists in a novel arrangement whereby the exit for the waste products of combustion is fixed in about the same horizontal plane with that part of the heating chamber at which the fuel is ignited, whereby the consumption of fuel is carried on without a direct draught through the heating chamber; the waste products of combustion escape from the combustion chamber only by passing downward below

the plane of ignition, and thence out below the lower edge of the "water leg." The specification is accompanied by drawings.—F. S.

*Improved Gases or Gaseous Mixtures for Use in the Production of Light, Heat, and Power.* E. Tatham, Balmain, New South Wales. Eng. Pat. 16,138, October 14, 1889. 4d.

THE improved gases or gaseous mixtures are called "Carburetted Hydro-oxy Gas" or "Bi-carburetted Hydro-oxy Gas." In practice they are produced in one way by charging the hydrocarbon gas or hydrocarbon vapour with "carburetted oxygen" as the coal-gas issues from its place of manufacture, and while still hot, but not above the temperature of, say, 300° F., and the proportions of the mixture are regulated according to the illuminating power required, that is, for a gas or gaseous mixture suitable for ordinary illuminating purposes, and for use in engines as a motive power, 2½ per cent. of oxygen is added to ordinary coal-gas of 16 candle power. It is preferable to add to gases of a greater specific gravity or containing a larger quantity of carbon than coal-gas an increased amount of the carburetted oxygen. The mixtures so produced are said to give a most brilliant light, and are more economical for heating and engine purposes than ordinary coal-gas.—F. S.

*Improvements in Coal-Gas and like Gases, and in the Manufacture thereof.* E. Tatham, Balmain, New South Wales. Eng. Pat. 16,142, October 14, 1889. 4d.

THE improvement consists in the admixture with coal-gas or similar gases of a reasonable quantity of oxygen during manufacture, preferably as it issues from the retorts, and in the conversion of the tar produced or other similar hydrocarbons into gas or vapour, which is admixed preferably while still hot with oxygen. (Compare Eng. Pat. 16,138 of 1889, preceding abstract).—F. S.

*Improvements in the Manufacture of Gas.* D. H. Knapp, Norwich, New York, U.S.A. Eng. Pat. 16,646, October 22, 1889. 6d.

A CYLINDRICAL retort is set upright in a furnace, and a hole in the cover allows a similar but smaller retort to hang suspended by a flange. The smaller retort has an upright pipe fixed to the bottom, and open at both ends. Oil being fed into the smaller retort becomes vaporised, and the vapours being conducted downwards by the upright pipe into the larger retort, are there converted into permanent gas for illuminating purposes.—G. H. B.

## IV.—COLOURING MATTERS AND DYES.

## PATENTS.

*Improvements in the Method of and Means for Concentrating or Evaporating and Distilling Solutions for the Production of Dyes and other Bodies.* J. Frost, Moldgreen. Eng. Pat. 1803, February 1, 1889. 8d.

See under I., page 167.

*The Production of New Azo-Dyes, applicable for Dyeing and Printing.* O. N. Witt, Charlottenburg, Germany. Eng. Pat. 2499, February 12, 1889. 6d.

THE patentee has discovered that  $\alpha$ - $\beta$ - $\alpha$ -dihydroxynaphthalene ( $\beta$ -naphthohydroquinone) will combine with diazo-compounds to form colouring matters capable of dyeing mordanted fabrics. In these combinations the diazo-compounds obtained from non-sulphonated amines are most suitable for preparing cotton dyestuffs, whilst the sulphonated compounds are used preferably in dyeing wool and silk. Ninety-three kilos. of aniline, 200 kilos. of hydrochloric acid (containing 37 per cent. of HCl), and 2,000 litres of water are diazotised at a temperature not exceeding 5° C. by the addition of an aqueous solution of 69 kilos. of sodium nitrite. This liquor is then run into a cold aqueous solution of 160 kilos. of dihydroxynaphthalene and 150 kilos. of crystallised sodium acetate in 2,000 litres of water. A dark orange precipitate is formed, which is filtered, washed and made into a paste with water. It may then be used for dyeing or printing on cotton in connexion with a suitable mordant. Alumina gives a bluish-pink, iron a greyish-violet, and chromium a purple. The following is an example of the method employed for preparing wool or silk dyestuffs:—184 kilos. of diazobenzene sulphonic acid (from sulphanilic acid) are suspended in water and added to the solution of dihydroxynaphthalene prepared as above. A dark orange solution results, and the dyestuff is salted out, forming an orange precipitate, which is filtered and dried. Its solution dyes wool mordanted with alum a dark bluish-red, whilst with chromium a bluish-purple. Other amines or their sulphonic acids may be employed in place of those already mentioned, such as toluidine, xyldine,  $\alpha$ - and  $\beta$ -naphthylamines, or the nitro- and hydroxy-derivatives of aniline, Brönner's  $\beta$ -naphthylamine sulphonic acid or Piria's naphthionic acid.—T. A. L.

*A New Colouring Matter for Dyeing and Printing Purposes, and its Method of Manufacture.* R. Guehn, Basle, Switzerland. Eng. Pat. 2635, February 14, 1889. 4d.

By heating dimethyl- or diethyl-*m*-amidophenol with succinic acid and zinc chloride, colouring matters are obtained which dye wool, silk and mordanted cotton red with a yellow fluorescence. 30 grms. of diethyl-*m*-amidophenol, 50 grms. of succinic acid, and 20 grms. of zinc chloride are heated for 15 minutes to 205°, or for 1—2 hours at 195°, allowed to cool, dissolved in 1 litre of water on the water-bath, and precipitated with 150 grms. of salt. The mother-liquor is decanted when cold, the precipitate again heated with 1 litre of water and 20 grms. of ammonium chloride, and reprecipitated with 150 grms. of salt. The mother-liquor is again decanted, and the semi-fluid residue dissolved in 10 cc. of hydrochloric acid and 1 litre of water, and evaporated to dryness. This colouring matter forms a very hygroscopic brownish-red powder soluble in water and spirit. The hydrochloride of the colouring matter obtained by heating equal weights of dimethyl-*m*-amidophenol, zinc chloride, and succinic acid anhydride to 190°—210°, forms green crystalline needles, also soluble in water and alcohol.

—T. A. L.

*Production of Triphenylmethane Colours Dyeing with the Aid of Mordants.* T. R. Shillito, London. From J. R. Geigy and Co., Basle, Switzerland. Eng. Pat. 3333, February 25, 1889. 4d.

A PROCESS for the synthesis of tricarboxylic acids of aurin and its homologues by oxidising salicylic acid or  $\beta$ -cresotinic acid (from *o*-cresol) together with bodies like methyl alcohol, formaldehyde, "methylal," dihydroxydiphenylmethanedicarboxylic acid, dihydroxyditolylmethanedicarboxylic acid in sulphuric acid solution with the aid of nitrous acid. Two kilos. of salicylic acid are dissolved in 15 kilos. of concentrated sulphuric acid and 4 kilos. of methyl alcohol. The solution is heated to about 70°, when 1.5 kilos. of sodium nitrite are added. After a short time the melt is poured into water, and the precipitate washed, neutralised with an alkali, and dried.—T. A. L.

*Manufacture of Azo Colouring Matters.* J. Imray, London. From "La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis," A. F. Poirrier and D. A. Rosenstiehl, Paris, France. Eng. Pat. 4825, March 19, 1889. 4d.

COLOURING matters giving very deep colours extending to black are obtained by diazotising the mono- and disulphonic acids of aniline, of the toluidines, xyldines and naphthylamines, combining them with  $\alpha$ -naphthylamine, rediazotising the compound obtained and combining it with the phenyl, tolyl, benzyl, xylyl, or naphthyl derivatives of *m*-phenylenediamine or with the corresponding secondary and tertiary derivatives of cresylene or "xenylenediamine." 30 kilos. of sodium  $\alpha$ -naphthylamine disulphonate are diazotised in an aqueous solution with 7 kilos. of sodium nitrite and 45 kilos. of hydrochloric acid and combined with 900 litres of a solution of  $\alpha$ -naphthylamine hydrochloride containing 14.3 kilos. of  $\alpha$ -naphthylamine. The compound thus obtained is again further diazotised by adding 20 kilos. of hydrochloric acid and subsequently 7 kilos. of sodium nitrite in 15 litres of water. The diazo compound which precipitates is filtered off and added as a paste to 26 kilos. of diphenyl-*m*-phenylene diamine in alcohol. After standing some hours the liquid is acidified and the colouring matter which precipitates is filtered off and converted into the sodium salt.—T. A. L.

*Manufacture of Colouring Matters giving Grey, Brown, and Analogous Tints.* J. Imray, London. From "La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis." Eng. Pat. 5032, March 22, 1889. 4d.

THE nitroso-derivatives of secondary or tertiary aromatic amines, when heated, form basic colouring matters varying in shade from brown to grey. 10 kilos. of nitrosodimethylaniline hydrochloride are dissolved in 50 litres of water and the solution boiled for three hours. After cooling the product is run into 100 litres of water and the colouring matter precipitated by the addition of zinc chloride. Alcohol or benzene, toluene, or other hydrocarbons may be substituted for the water, and in place of dimethylaniline the nitroso-derivatives of other tertiary and secondary amines may be employed. The colouring matters form brown powders soluble in water, alcohol and acids. Their solutions are precipitated by alkalis and alkaline carbonates giving brown flakes soluble in hot and insoluble in cold water.—T. A. L.

*Improvements in Colouring Matters.* H. H. Leigh, London. From R. G. Williams, Albany, U.S.A. Eng. Pat. 11,795, July 24, 1889. 6d.

A PROCESS for obtaining cotton dyestuffs by combining one molecule of a tetrazo compound with two molecules of the alkylised acids of the orchella lichens or compounds of the same, and also by combining one molecule of a tetrazo compound with one molecule of a phenol or amine and reacting with this intermediate compound on one molecule of the alkylised acids of the orchella lichens. These acids

can be obtained by the direct action of alcohols on the lichens or else by digesting the orchella lichens for a short time with water in presence of lime, filtering and precipitating the orsellinic and other acids by the addition of hydrochloric acid. The acids thus obtained are filtered off, dried at a low temperature and boiled with an alcohol in order to produce the alkylised derivative. A colouring matter which dyes unmordanted cotton a scarlet shade from an alkaline or soap bath is obtained by diazotising 28 lb. of benzdine sulphate in the usual manner and running the solution into 36.4 lb. of the methylated acids of the lichens, 100 lb. of caustic soda and 100 gallons of water. The dye-stuff forms immediately and is salted out, pressed, and dried. The following is an example of the method for obtaining a mixed azo colour. 30.2 lb. of toluidine sulphate are diazotised and run into 28 lb. of the sodium salt of  $\alpha$ -naphthylamine mono-sulphonic acid, 30 lb. of sodium acetate and 100 gallons of water. The mixture is well stirred, and when the intermediate product is formed it is run into a solution of 18.2 lb. of the methylated lichen acids and 100 lb. of caustic soda. The colouring matter thus formed is similar to Benzopurpurin 4 B, but is faster to light.—T. A. L.

*Improvements in Dye Colours.* H. H. Leigh, London, From R. G. Williams, Albany, U.S.A. Eng. Pat. 14,294, September 10, 1889. 6d.

This is an extension of Eng. Pat. 12,767, 1889 (this Journal, 1889, 981), and describes the preparation of isomeric intermediate compounds which will combine with amines and phenols. The following example illustrates the method employed: 32 lb. of toluidine sulphate are diazotised with 14 lb. of sodium nitrite and combined with 25 lb. of sodium naphthionate in presence of sodium acetate. This compound is then combined with the diazo compound from 25 lb. of naphthionic acid, and when the combination is complete 25 lb. more of sodium naphthionate are added, and the mixture stirred until the colour is completely formed. The chief claim is substantially as follows: The production of colouring matters by combining one molecule of a tetrazo compound with one molecule of an amine, then combining one molecule of a diazotised amine with the primary intermediate product thus produced, and afterwards reacting on the secondary intermediate product thus obtained with one molecule of an amine or phenol.

—T. A. L.

*Production of New Blue Colouring Matters.* S. Pitt, Sutton. From L. Casella & Co., Frankfort-on-the-Maine, Germany. Eng. Pat. 16,698, October 22, 1889. 4d.

BLUE colouring matters easily soluble in water are produced by the action of *p*-phenylene or *p*-toluylene diamine on certain basic substances which on reduction only yield polyamines. Those which have given the best results are the triamido-azobenzene (Ger. Pat. 32,502), and diamido-azoxybenzene (Ger. Pat. 44,045). The triamido-azobenzene has the formula  $(p\text{-NH}_2\text{C}_6\text{H}_4\text{N}_2\text{C}_6\text{H}_4\text{NH}_2)_3(o \text{ and } p)$ , and is obtained by the action of *p*-amidodiazobenzene on *m*-phenylenediamine. 10 kilos. of the hydrochloride of this base and an equal weight of *p*-phenylenediamine are heated for three hours to 130°–140°, and then for one hour to 160°–170° with agitation. The melt is dissolved in dilute hydrochloric acid, and the colouring matter precipitated with salt as a dark blue powder soluble in 5 times its weight of boiling water, and in 11 times its weight of water at 20°. It dyes mordanted cotton a deep blue fast to light and washing. The second method is to convert diamido-azobenzene ( $m\text{-NH}_2\text{C}_6\text{H}_4\text{N}_2\text{O}$ ) into its hydrochloride and mix it with *p*-phenylenediamine in the proportion of 1 to 3 equivalents, heating the mixture to 160°. The operation is finished in 3–6 hours, water being given off, and the melt is sufficiently pure to be used directly. It may be purified by dissolving it in dilute hydrochloric acid and precipitating with salt.—T. A. L.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

### PATENT.

*Improvements in and relating to a New and Useful Fibre Produced from the Leaves or Needles of the Pines Australis and other Coniferous Trees.* W. Latimer, Wilmington, North Carolina, U.S.A. Eng. Pat. 13,127, August 20, 1889. 6d.

THE acicular leaves of the pine are first treated with an alkaline solution, washed and then passed through a decorticating machine, preferably that designed for the purpose (U.S. Patent 315,666, April 11, 1885). The fibre so prepared is carded or combed in any suitable machine, but preferably in that already mentioned, and is then dried, when it is ready to be spun and woven.—E. J. B.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

### PATENTS.

*Improved Apparatus for Dyeing and Washing Hats and other Articles, applicable also to Veneering Hats.* T. Wareham, Toronto, Canada. Eng. Pat. 14,606, October 11, 1888. 8d.

It is claimed that by means of this invention, which cannot be understood without reference to the drawings accompanying the specification, the operations of mordanting, rinsing, dyeing, exposing to the atmosphere, and veneering can be successively and uninterruptedly effected.—E. B.

*Improvements in the Manufacture of Paperhangings, Curtains, Carpets, and other Articles or Coverings from Jute.* H. Sauvage, Paris, France. Eng. Pat. 17,574, December 3, 1888. 4d.

JUTE textiles are rendered suitable for wall decorations, carpets, &c., by dyeing or printing the same after they have undergone the following preparation: scouring with alkalis, bleaching with "chlorozone," shearing, and stiffening with Caragheen moss and dextrin.—E. B.

*An Improved Process for Dyeing Blue.* E. Edwards, London. From Standaert Brothers, Hamme, Belgium. Eng. Pat. 18,709, December 21, 1888. 4d.

A SHADE of blue resembling indigo is obtained on cotton by boiling the cotton material with a solution of extract of logwood and "soda salt," then working in a cold bath of ferrous sulphate, rinsing, passing again into the first bath, and tinting in a bath containing soap, salt, or sulphate of soda, and a colouring matter such as aniline blue. After being immersed in this bath for about an hour the material is rinsed and dried.—E. B.

*Improvements in and connected with Indigo Dyeing.* J. Cowan, Glasgow. Eng. Pat. 18,904, December 27, 1888. 6d.

INDIGO in a dry state is ground with zinc oxide or zinc powder, crystallised sugar and potassium carbonate. The mixture is suitable for making into parcels for sale. To set a vat the mixture is placed in a tub, water is added and then bisulphite of soda. The reduced indigo so prepared may, in a concentrated state, be supplied to dyers ready for their use. Instead of potassium carbonate other alkalis and alkaline salts may be used, and various other sugars are mentioned besides crystallised sugar. Sulphuric acid may, according to option, be added before or along with the bisulphite of soda.—E. B.

*Processes for the Manufacture of New Chrome Mordanting Substances, and for the Application thereof for Dyeing and Printing Purposes.* W. L. Wise, London. From M. von Gallois, Hoechst a/Main, Germany. Eng. Pat. 376, January 8, 1889. 6d.

NORMAL chromium chromate,  $\text{Cr}_2(\text{CrO}_4)_3$ , is prepared by dissolving chromic hydrate (1 mol.) in chromic acid (3 mols.); a basic chromium sulphate-chromate, of the composition  $\text{Cr}_2(\text{SO}_4)(\text{CrO}_4)(\text{OH})_2$ , is obtained by dissolving excess of chromic hydrate in a mixture of sulphuric and chromic acids or by double decomposition between solutions of basic chromium sulphate and potassium or sodium bichromate. An addition of magnesium or sodium acetate is made to these solutions before they are used. In mordanting for yarn or piece-dyeing the material is impregnated with the solution, squeezed, dried and aged or steamed. A printing colour is made by boiling and thickening a solution of basic chromium sulphate, cooling partially and adding potassium chromate and magnesium acetate, or the sulphate-chromate of chromium, made from the hydrate, may be used. The printed goods are dried and aged or steamed. Resists or discharges may be effected by printing thickened mixtures of organic acids, and when these are applied it is recommended to pass the pieces through a weak bath of carbonate of soda before dyeing.—E. B.

*Improvements in Machinery for Printing Floorcloths or similar Materials.* E. Ostlere, Kirkealdy, and A. M. Strathern, Springburn. Eng. Pat. 1283, January 24, 1889. 11d.

THIS invention cannot be properly explained without reference to the drawings which accompany the specification.—E. B.

*Improvements relating to the Washing or Scouring of Wool, Cotton Waste, and other Dirty Materials or Fabrics.* J. Portella, Hornsey. Eng. Pat. 1453, January 26, 1889. 6d.

THE use is claimed of a scouring mixture composed of soap, ammonia and turpentine. An advantage attending the use of such a mixture is that the more valuable impurities, such as lanolin in wool and the oily matters in cotton waste, can be easily recovered. When the mixture is applied for the purpose of cleaning cotton waste a further addition of potash or soda is made.—E. B.

*Improvements in Machinery for Printing Canvas, Floorcloth, Linoleum, and other Textile Fabrics specially prepared therefor.* L. Heyde, Dundee. Eng. Pat. 1759, January 31, 1889. 6d.

THE improvements in question consist in the combination of both block and roller printing in the same machine. The printing rollers are mounted in suitable framework on the same level. The material to be printed passes under the printing rollers and is pressed against the same by a series of pressure rollers covered with an endless travelling band. It then passes on to the block printing machine where the remainder of the pattern is printed. A claim is made for a method of supplying the colour to the blocks. For details of the mechanical arrangements the original specification must be consulted.—E. B.

*A Cold Process of Dyeing Hair and Feathers by means of Paraphenylenediamine or similar Bases.* H. Erdmann, Halle, Germany. Eng. Pat. 2525, February 13, 1889. 4d.

AFTER imbuing the feathers or hair with the solution of a para-amidophenol or a paradiamine, they are treated with a solution of either benzo- or tolu-quinone or an oxidising agent, such as hydrogen peroxide, ferric chloride or a permanganate. The following phenols and amines are specified; para-amidophenol, symmetrical triamidophenol, paraphenylenediamine, toluenyleneparadiamine, dimethylparaphenylenediamine and naphthylenediamine (1:5). In this way fast shades of brown to black are produced.—E. B.

*Improvements in Dyeing Mixed Woven Fabrics.* T. Ingham, Manchester. Eng. Pat. 2984, February 20, 1889. 6d.

By means of this invention animal and vegetable fibres in mixed fabrics can be simultaneously dyed black and other colours. The scoured goods are passed full width through a bath of one or more of the following colouring matters:—logwood, catechu, fustic, bark, berries, peachwood, with or without coal-tar dyes such as Benzo-azurine. After squeezing and drying, the colouring matter is oxidised and fixed by passing the cloth in the open state through a solution of any or mixture of some of the following:—bichromate of potash, bichromate of soda, bichromate of ammonia, chromic acid, nitrate of iron, sulphate of iron, sulphate of copper, carbonate of soda, or sulphate of soda. The dyed cloth is then rinsed or cleansed first in cold water and then in hot, or passed through a bath of carbonate of ammonia, carbonate of soda, or soap, finally being rinsed again in cold water before drying. Examples are given of the application of this method for dyeing black, blue-black, brown, and bronze, on fabrics composed of cotton and wool.—E. B.

*Improved Cleansing, Scouring, and Bleaching Compound for Wool and other Fabrics, also applicable to Cleansing Purposes generally.* A. H. Parker, London. Eng. Pat. 9410, June 6, 1889. 4d.

THE compound consists of a mixture of "pearlash, borax, ammonia, soft soap, Scotch soda, and Jeyes' disinfectant."—E. B.

*Improvements in Dye-extracting Apparatus.* F. Rhodes, Westfield. Eng. Pat. 15,558, October 3, 1889. 6d.

THIS invention relates to an improved form of apparatus used for extracting dye-woods. The improvements in question consist in employing, in combination with an ordinary dye-vat and appliances for heating and raising water, an extracting vessel of rectangular or cylindrical shape, one end of which is permanently closed, the other end being provided with a moveable steam-tight door. Water or liquor from the dye-vat is forced or pumped to the top of this vessel, and after passing through the dye-wood contained in it, flows back into the dye-vat. Several modifications of the arrangements are described.—E. B.

*Improvements in Apparatus for Dyeing Skeins.* J. C. Newburn, London. From La Société Grandire et Fils, Bolbec, France. Eng. Pat. 15,881, October 9, 1889. 6d.

THE skeins U are hung on the triangular reels J carried by the platform H, which slides on the square shaft C and is

counterbalanced by G. On the axis of each reel is fixed a pinion which, when H is lowered, gears with a crown wheel on the fixed platform N, so that the revolution of the platform H causes the rotation of the reels on their own axes. K K are bars for lowering the platform, O the annular dye vat, and M the footstep bearing for the vertical shaft. Instead of counter-balancing the platform, the shaft and the boss of the platform may be screwed, and friction rollers working on the edge of the vat may be substituted for the pinions on the reels and crown wheel on the fixed platform. In the Figure the platform is shown raised, in working the platform being lowered and fixed to ensure the contact of the pinions and crown wheel.—O. H.

*Improvements in Machines for Dyeing Cotton and Analogous Materials.* L. Weldon, Amsterdam, U.S.A. Eng. Pat. 18,973, November 26, 1889. 6d.

This invention relates to machines for dyeing raw or unmanufactured cotton. The improved machine consists of a perforated rotary cylinder or cage, which is placed in the dye-vat, so as to be partially submerged. The cylinder is provided with compartments, and at the centre of each compartment there is extended a rod armed with laterally-projecting pins or wings, termed a "breaker-bar." During the working of the machine the cotton contained in the compartments falls on the "breaker-bars," and is well distributed, so that even dyeing results.—E. B.

## VII.—ACIDS, ALKALIS, AND SALTS.

*Report by G. Wyss to the "Société Industrielle de Mulhouse" upon a Paper by E. Sorel, entitled "Etudes sur la fabrication de l'acide sulfurique."* Bull. Soc. Ind. Mulhouse, 1889, 237—239.

In his historical résumé of the work already done by other workers in this field, Sorel has failed to mention some of Lunge's researches, and others of Hurter and Eschellmann.

Sorel has set himself the task of demonstrating that temperature plays a preponderating part in the formation of sulphuric acid, and he has brought to light the important fact that it is the fall of temperature at the walls of the chambers that restarts the process of manufacture. This function he has thoroughly studied, and his determination of the tension of aqueous vapour in the presence of sulphuric acid, and of the tension of the nitrous compounds in solution in sulphuric acid, are researches of fundamental importance, which must be taken into account in all future investigation in this direction.

Nevertheless, his theory of the sulphuric acid process is not new. Lunge published an identical view in 1885 (Ber. 18, 1391), and again, in a more complete form in 1887 (Ber. 21, 67; this Journal, 1888, 208), at about the same time that Sorel's memoir was presented at Cherbourg.

Among the reactions instanced as primary ones the following two—

should rather be looked upon as secondary. The author of this report points out also that Davy's theory is based upon the existence of hyponitric acid (nitrogen tetroxide) in the chamber gases, and that for this reason it is untenable, and not because, as stated by Sorel, it admits the formation of chamber crystals. In fact, the chamber crystals are nothing else but nitrosulphonic acid.

Lunge and Sorel are, therefore, the first propounders of the very probable theory that the sulphuric acid process does not depend essentially upon the reduction and oxidation

of the oxides of nitrogen, but upon the formation of nitrosulphonic acid and its decomposition by water, according to the equations—

The explanation of the reactions in the Glover tower are most interesting, and it can no longer be admitted that the affinity of NO for oxygen can produce of itself the formation of sulphuric acid in the tower, when the extremely short time, as calculated by Sorel, that the gases remain in the active zone of the tower is taken into consideration. The interpretation of the reactions in the first chamber is highly plausible.

It is evident that the cooling effect of the pipes connecting the chambers has a remarkable influence in facilitating the restarting of the process at the entrance of the second chamber. In this view Sorel agrees with Schertel (Chem. Ind. 12, 80; this Journal, 1889, 283). Lunge has ascribed this restarting of the process to the more complete mixing of the gases which would be brought about by passing through the pipes.

The application of his theory that Sorel proposes is certainly a possible one, and an economy in the first cost of plant will be realised by carrying out his ideas or in modifying their details. At any rate, it should be taken into consideration by every manufacturer desirous of keeping his methods of working up to date.—H. S. P.

*The Manufacture of Sulphuric Acid.* E. Sorel. Bull. Soc. Ind. Mulhouse, 1889, 240—293.

AFTER a short summary of the history of the sulphuric acid manufacture, and pointing out the progress that manufacturers have made up to the present time in the direction of economical working, showing that before the introduction of the Gay-Lussac and Glover towers only 1.75 kilos. of monohydrated acid ( $\text{H}_2\text{SO}_4$ ) per cubic metre of chamber space were made as compared with 4.25 kilos. per cubic metre to-day, the author draws attention to the accompanying diagram, which is taken from a publication by Lunge and Naef (Chem. Ind. 1884, 5; this Journal, 1884, 633), and which shows the curves representing the progress of the oxidation of the  $\text{SO}_2$  in the chambers of the Uetikon works. The ordinates of these curves represent the successive amounts of  $\text{SO}_2$  that have been oxidised per 100 parts of  $\text{SO}_2$  introduced into the chamber, and the abscissae the distances from the front wall of the first chamber. It is seen that the back parts of the apparatus do very little work, and that there are zones where the process is almost at a standstill. According to the author's own experience these curves fairly represent the general course of the process in the lead chamber. There is, therefore, room here for a further economy. But to know how to effect this, it is necessary to have a precise knowledge of the reactions that go on in the chamber, and of the causes which can modify these reactions. Upon this point the author maintains that the manufacturer has made scarcely any advance since the time of Clément and Desormes (1793), and he quotes from Scheurer-Kestner's article in Wurtz's dictionary to show this: "L'acide nitrique n'est que l'instrument de l'oxygénation complète du soufre: c'est sa base, le gaz nitreux, qui prend l'oxygène à l'air atmosphérique pour l'offrir dans un état qui lui convienne." After such an avowal of impotence, one can understand why manufacturers have had to renounce all originality of method, and to content themselves with perfecting themselves in the use of the apparatus bequeathed to them by their predecessors.

In considering the problem of the sulphuric acid process, the first thing to be noted is, that because the oxides of nitrogen act as a vehicle of oxygen, now removing it from the air and now giving it up to the  $\text{SO}_2$ , they must exist in a condition allowing of their easy dissociation. There is, therefore, no question of sharply defined reactions taking

place, no matter what physico-chemical conditions may exist in the surrounding medium, but rather of a series of transformations absolutely dependent upon the medium that surrounds the reacting materials.

If it were possible to unite all the most favourable conditions in every part of the chamber, the speed of oxidation of the  $\text{SO}_2$  at any part would be proportional to the  $\text{SO}_2$  remaining

in the gases as they traversed that part. The two plain-line curves in Lunge and Naef's diagram show the theoretical curves corresponding to a final escape of  $\text{SO}_2$  equal to 0.5 per cent. of sulphur burnt in one case and to 4 per cent. in the other; the broken line curves show the experimental data actually obtained for losses equal to 0.4 per cent. and 3.7 per cent. of sulphur burnt.

The theoretical and practical curves show a general concordance, but the differences that they do show are so sharp that it is not possible to look upon them as the result of chance. It is clear that we have to deal with conditions in certain zones of the chamber which hinder the progress of the reactions.

The conditions to be investigated are dependent upon variations in:—

- Temperature.
- Tension of aqueous vapour.
- Capacity of the nitrous products to combine with sulphuric acid.
- The relative proportions of oxygen and sulphurous acid in relation to the nitrous compounds.
- The reducing energy of sulphurous acid in relation to the nitrous compounds.

It is quite clear that oxidation and reduction of the nitrous compounds cannot take place simultaneously and in the same spot, nor can they occur in succession in the same spot unless the state of the surrounding medium at that spot varies.

A. *Temperature*.—There are three causes tending to produce a rise of temperature:—

- The continuous introduction of hot gases and of steam.
- The heat generated by the chemical reactions.
- The condensation of a part of the gaseous products.

The cause tending to produce a *fall* of temperature is the continuous radiation from the chamber walls. For each section of the chamber, therefore, a certain state of equilibrium will become established, and since of the three causes of rise of temperature that caused by the chemical reactions is the chief, the temperature inside the chamber will vary in degree above that of the air according as the chemical reactions are more or less intense in one part than the other. The temperature at the front of the chamber is therefore the highest.

But the walls do not transmit the whole of the heat produced in any one section, and consequently the temperature of the inner part of the chamber does not follow the same law, dependent upon the energy of the chemical reactions, and, as a matter of fact, at a height of 1.5 metres

from the floor of a No. 1 chamber there is only a difference of about 2° C. between the front and back of the chamber. At the surfaces of the walls, however, the gases are necessarily cooled. Moreover, within the chamber certain strata seem to be the chief seats of chemical activity, and sharp rises of temperature are indicated at such parts. Consequently, in a transverse section of a chamber we find different temperatures according to where the thermometer is plunged.

In a set producing about two kilos. of  $\text{H}_2\text{SO}_4$  per cubic metre the following temperatures were indicated in the first chamber, at points 1.5, 11.5, and 21.5 metres respectively from the end-wall at the front of the chamber. At each distance two holes were made in the top of the chamber, one in the axis of the chamber (designated by *a*) and the other .5 metre from the side (designated *b*). The experiments were made in the summer, so that the temperatures are relatively very high. The temperature at the top of the chamber 0.1 metre from the wall was 87°.

	1.5 m. from fore-end.		11.5 m. from fore-end.		21.5 m. from fore-end.	
	<i>a.</i>	<i>b.</i>	<i>a.</i>	<i>b.</i>	<i>a.</i>	<i>b.</i>
0.50 m. from top of chamber.....	86	76	79.5	90	74	85
3.50 m. from top of chamber.....	86	81	88.5	88.5	86	85
6.00 m. from top of chamber.....	85.5	83	82	83	84	82
6.15 m. from top of chamber, i.e., at 0.1 m. above the acid on the floor.....	84	79	85.5	85.5	84.5	79.5

Thus in spite of the radiations from the side we find the temperature at certain parts near it notably higher than the interior temperature at the axis.

In a set making 3.25 kilos.  $\text{H}_2\text{SO}_4$  per cubic metre, in which, of course, the temperatures were consequently very high, the author found in the first chamber, at 16 metres from the fore-end (0.4 of its total length), the following temperatures:—

(TEMPERATURE OF THE GASES IN THE INLET  
PIPE, 82.5°)

	At 0.15 m. from side.	At 0.50 m. from side.	In the Axis.
0.4 m. from top .....	94°	87.7°	88.4°
1.5 m. " .....	..	87°	88.9°
1.6 m. from floor.....	91°	..	..
0.5 m. " .....	..	88°	90.2°

At this distance from the fore-end, the highest temperature is seen to be close to the side.

In the same chamber the following temperatures were also noted:—

On the side wall.....	78.5 to 79.7
At 0.02 m. from side.....	84
0.04 m. " .....	91
0.06 m. " .....	95.25
0.08 m. " .....	95.25
0.10 m. " .....	98.5
0.12 m. " .....	97.3

The cooling influence of the side wall is therefore only felt close to the wall.

Such variations in temperature as are here indicated must cause movements in the gases which thoroughly mix them and give them a great uniformity of composition in each section. The author would agree with Abraham (Dingl. Polyt. J. 245, 414), that each molecule travels in a spiral round a horizontal axis from one extremity of the chamber to the other.

In these movements of the gases, the particles of liquid in suspension pass into zones of different temperatures, and consequently change their state of concentration and richness in nitrous products at each instant, so as to bring themselves into equilibrium with that portion of the gaseous atmosphere which surrounds them. Therein lies the secret of the rationale of the sulphuric acid process.

*B. Tension of Aqueous Vapour in presence of Dilute Sulphuric Acid.*—Heretofore we have only Regnault's experiments on this subject. But he only carried them up to a temperature of 35° C., which is much too low for the purpose under discussion. The author has extended his investigations to a temperature of 95°. Briefly stated, his method, which is more fully described in the original, consisted in aspirating an accurately measured volume of air very slowly over pumice-stone saturated with sulphuric acid of known strength, maintained at a constant and known temperature, and trapping the water-vapour carried over by the air, in a weighed Liebig's tube, filled with concentrated  $\text{H}_2\text{SO}_4$ .

The experiments were made at 45°, 60°, 77°, and 95°, with acids containing 50.25 per cent., 56.75 per cent., 65.75 per cent., 71.73 per cent., and 83.52 per cent. of pure monohydrated  $\text{H}_2\text{SO}_4$ . The results obtained and those obtained by Regnault for lower temperatures were expressed in curves, and the numbers contained in the accompanying table were then deduced by graphic interpolation.

TENSION OF AQUEOUS VAPOUR EMITTED BY DILUTE SULPHURIC ACID.

It can be now seen how the differences of temperature shown to exist in the chamber will affect the concentration of the acid that is either held in suspension in the gases or collected in a thin film upon the walls.

Thus, referring to the temperatures given above at 16 metres from the fore-end of the chamber; the acid which was collected from the wall at this point showed an average of 52.5° B. = 66 per cent.  $\text{H}_2\text{SO}_4$ , and the temperature on the chamber side was 78.5° C., which corresponds to a vapour-tension of 39 mm. At the interior temperature of 95°, acid having the same vapour-tension as this would show 56.6° B., and contain 72.33 per cent.  $\text{H}_2\text{SO}_4$ . This agrees with practical experience, so that it may be concluded that the acids collected at different parts of the same transverse section are in equilibrium as regards the tension of the water-vapour they emit.

*C. Tension of the Nitrous Products in presence of Dilute Sulphuric Acid at Various Temperatures.*—By nitrous products the author designates all the oxides of nitrogen from nitric oxide (NO) to nitric acid, inclusive. He summarises the work done by previous chemists, chiefly by Lunge and Weber, and points out that they have shown that, in the presence of sulphuric acid in a suitable state of concentration, the oxides of nitrogen in contact with oxygen form nitrous acid, even when the oxygen is in excess, which then forms with the sulphuric acid a relatively stable compound. Further, Lunge has shown that nitrous acid which had previously been considered as quite unstable is nevertheless capable of existing at a temperature of 150°, and forms, with suitably concentrated sulphuric acid, a very stable compound under certain conditions, not reducible by sulphurous acid.

The author has attempted to show the conditions of equilibrium of this compound at various temperatures; and in order to avoid the influence of oxidising or reducing agents, he has employed an atmosphere of nitrogen.

He allowed a mixture of dilute sulphuric acid and of pure nitrous acid dissolved in concentrated sulphuric acid to flow, drop by drop, through a spiral tube 5 metres long immersed in a water-bath at a constant temperature, and passed a current of nitrogen in a contrary direction through the spiral; the quantity of nitrous acid in the mixture of acids before and after passing through the tube, and the volume of the nitrogen drawn through the tube being severally accurately determined, he was able to calculate the weight of nitrous acid given up by the mixture of acids used.

The following table shows the results he has obtained:—

Sp. Gr. of Sulphuric Acid.	Grammes $\text{N}_2\text{O}_3$ per Litre.	1 Litre of Nitrogen measured at 0° and 760 mm. Abstracts <i>n</i> mgrs. of $\text{N}_2\text{O}_3$ at a Temperature of $t^\circ$

He intends to continue the research to see if a law connecting these results can be found. At present the conclusion can only be drawn that the acid mixture behaves like a solution of nitrous acid in sulphuric acid, rather than as a compound. The dissolution of the nitrous acid is very rapid with rise of temperature, and the richness of the sulphuric acid in nitrous acid is probably a function of the tension of the nitrous compounds in the surrounding atmosphere.

When the degree of dilution is moderately large, the tension of the nitrous acid at high temperatures is sensibly proportional to the richness of the sulphuric acid solution.

*D. Influence of relative Proportions of Oxygen and Sulphurous Acid upon the Nitrous Compounds.*—The tension of the nitrous products in the gases being related to the degree of concentration of the sulphuric acid and to the richness of the solution of nitrous acid in sulphuric acid, it is clear that the latter solution will become richer or poorer according to whether the oxides of nitrogen in the gases are able to pass into the form of nitrous acid or not.

Lunge has shown that, in the presence of concentrated sulphuric acid, NO and O, even when the O is in excess, only produce nitrous acid, which then enters into solution.

On the other hand, pure sulphurous acid, acting upon warm nitrous sulphuric acid, reduces the dissolved nitrous acid just as it reduces the gaseous acid.

If, then, we have a mixture of sulphurous acid, oxygen, and nitric oxide in the presence of nitrous sulphuric acid, there will either be a reduction of the dissolved  $\text{N}_2\text{O}_3$ , or an oxidation of the NO, dependent upon the temperature, the degree of concentration of the sulphuric acid, and the relative proportions of sulphurous acid, oxygen, and of NO in the mixture.

Practice has shown that in extreme cases, with a high temperature, absence of oxygen, and excess of water, a reduction takes place, whilst when the oxygen is in excess, the acid concentrated, and the temperature low, there is oxidation.

The author has investigated, to a certain extent, the intermediate cases.

He caused measured quantities of a mixture of sulphurous acid, oxygen, nitric oxide, and water-vapour in known proportions to come in contact with nitrous sulphuric acid of various specific gravities, and containing various known quantities of nitrous acid at different temperatures, and

then determined the resulting amount of nitrous acid in the sulphuric acid.

The experiments showed that the reactions were complicated. The following points were, however, made clear. When the sulphuric acid has a higher specific gravity than 1.630, then sulphurous acid does not reduce nitrous acid, but forms with it in the presence of sulphuric acid a solution of nitrosulphonic acid, provided that there is an excess of oxygen and a greater quantity of nitrous acid present in the gases than corresponds to the tension of the nitrous acid held in solution by the sulphuric acid. In all other cases a reduction takes place. And that this statement also holds good when the specific gravity of the sulphuric acid is below 1.600, but only to a certain low limit of temperature (about 70° C.), beyond which a reduction takes place, even in the presence of an excess of oxygen and of nitrous acid.

*E. The Reducing Energy of Sulphurous Acid in Relation to the Oxides of Nitrogen.*—The author merely draws attention to the results already obtained, chiefly by Winekler, Weber, and Lunge.

Mixtures of NO, N<sub>2</sub>O<sub>3</sub>, and N<sub>2</sub>O<sub>4</sub> are not reduced by SO<sub>2</sub> if the gases are dry. A small quantity of water causes the formation of crystals of nitrosulphonic acid at the expense of the higher oxides; the NO is not altered. A large quantity of water produces the formation of H<sub>2</sub>SO<sub>4</sub>, but in this case NO is reduced even in presence of excess of O. With dilute sulphuric acid instead of water, there is no reduction of NO at from 40°–50° C. if the acid be not below sp. gr. 1.32. A reduction takes place if the acid be weaker than this. When the acid is concentrated the reduction becomes more difficult as the concentration is greater.

Nitric acid much diluted with water or with sulphuric acid below sp. gr. 1.36 is not reduced at the ordinary temperature, but heat causes its reduction. When the density of the sulphuric acid is above 1.4, reduction takes place in the cold accompanied by the formation of N<sub>2</sub>O<sub>3</sub>; reduction then becomes more difficult as the concentration of the solvent increases. In an atmosphere rich in oxides of nitrogen, a little nitric acid is found to be dissolved along with N<sub>2</sub>O<sub>3</sub>.

*Theory of the Sulphuric Acid Process.*—It has been shown in the preceding that a solution of nitrous acid in sulphuric acid liberates a certain quantity of nitrous acid in an inert atmosphere. The quantity liberated depends upon the concentration of the sulphuric acid, the richness of the solution (below a certain degree of concentration of the sulphuric acid), and upon the temperature. Let us eliminate a certain quantity of the nitrous acid, either by actual removal of it or by reducing some of it to nitric oxide. The solution will then liberate a fresh quantity of nitrous acid and will go on impoverishing itself if this be again removed.

On the other hand, if we reoxidise the NO the solution may take up again the N<sub>2</sub>O<sub>3</sub> formed.

If we raise the temperature of the solution the tension of the nitrous acid dissolved rapidly increases. If we dilute the solution the same result is observed, but the tension increases more rapidly.

It follows then that if, in an atmosphere containing a definite amount of nitrous acid, we bring together two solutions of nitrous acid in sulphuric acid at the same temperature, the one a solution in concentrated acid, and the other in dilute acid, the more concentrated acid solution will be enriched at the expense of the other. This might also take place if the temperature of the stronger acid were higher (to a certain limit) than that of the weaker acid.

Sulphurous acid does not hinder the dissolving of nitrous acid in sulphuric acid when the latter is of a suitable concentration, and if there is an excess of oxygen present, so long as the tension of the nitrous acid existing in the gaseous mixture, or capable of being formed in it by the oxidation of NO, is greater than the tension of the nitrous acid dissolved already in the sulphuric acid. But if the tension of the nitrous acid in the gases be less than that of the solution, then sulphurous acid facilitates the decomposition of the solution, whether we dilute the acid or raise the temperature.

Now let us suppose that we have a certain quantity of sulphuric acid of, say, 57° B., containing such an amount of nitrous acid as to be in equilibrium with the surrounding atmosphere at the temperature there existing, and let us suppose that this sulphuric acid is held in the state of mist in the atmosphere. Let us isolate a certain volume of the gaseous mass and cool it under constant pressure. A portion of the aqueous vapour in the atmosphere will thus be condensed both by the fall of temperature and by the contraction of the volume, and will consequently dilute the sulphuric acid suspended in the atmosphere. This dilution will at once destroy the equilibrium existing between the nitrous acid dissolved and that in the atmosphere, the sulphuric acid will liberate nitrous acid which will then be reduced by the sulphurous acid present, with formation of nitric oxide and sulphuric acid. The sulphuric acid formed will tend to again concentrate the acid solution. The reaction will therefore tend to stop when the quantity of acid formed and that submitted to the experiment approach each other.

Now let us assume that this same gaseous mass is brought back to the initial temperature. The acid will then liberate water-vapour so as to bring itself into equilibrium with the conditions of the higher temperature, and will become again concentrated to 57° B. It will then be able to fix more nitrous acid, and will thus determine the re-oxidation of the nitric oxide, provided there is still a sufficient quantity of oxygen present.

In these variations of concentration and of temperature we find the immediate cause that brings about the successive reduction and oxidation of the oxides of nitrogen and the consequent rapid oxidation of sulphurous acid.

The following equations represent the reactions:—

#### 1ST SERIES.—FORMATION OF NITROSULPHONIC ACID.

##### a. By Direct and Simultaneous Oxidation.

##### b. By Indirect Oxidation of SO<sub>2</sub>.

#### 2ND SERIES.—LIBERATION OF N<sub>2</sub>O<sub>3</sub>.

To these may be added the less important or accidental reactions:—

The author remarks that his theory resembles those of Davy and Winekler, but differs from them in not assuming the intervention of any body whose existence in the chambers is hypothetical. Davy's theory rests upon the formation of chamber crystals, which only are found in very abnormal working; that of Winkler depends upon the formation of hyponitric acid (N<sub>2</sub>O<sub>4</sub>) which is only found under particular and well-known conditions. (Compare preceding abstract.)

The author then applies his theory to explain in detail the whole sulphuric acid process from the burners to the Gay-Lussac tower.

*The Glover Tower.*—Not only is the acid introduced into the Glover tower, denitrated and concentrated, but there takes place there a formation of sulphuric acid equal to 16 or 18 per cent. of the total production in small towers, and to as much as 24 per cent. in large towers (having a capacity of 8 or 10 cubic metres per 100 kilos of

sulphur burnt), provided there is a plentiful supply of nitrous products.

According to Scheurer-Kestner (Compt. Rend. 1884, November 24, and 1885, March 2; this Journal, 1885, 457) from 1 to 9 per cent. of this sulphuric acid is contained as  $\text{SO}_3$  in the burner gases, which becomes hydrated in the Glover tower. Taking the higher figure, 9 per cent., this leaves an actual production of sulphuric acid in the Glover tower of from 9 to 16 per cent.

These amounts correspond to an introduction of a quantity of recovered nitrous acid equal to 8 or 10 parts of commercial nitrate of soda in the one case, and to 22 or 24 parts of nitrate of soda per 100 parts of sulphur burnt, in the second case. In both cases it may be assumed that nitrous acid from 2.5 parts of nitrate of soda per 100 parts of sulphur burnt are introduced to make up for loss. We have, therefore, the following quantities of available oxygen:—

Oxygen from recovered nitrous acid.....	0.74 or 0.90	1.60	2.21	
Oxygen from 2.5 parts NaNO <sub>3</sub> .....	0.22	0.22	0.22	
Total oxygen per 100 of sulphur burnt.....	0.96	1.12	1.82	2.43

Since 16 parts of oxygen are required to oxidise 32 parts of sulphur from  $\text{SO}_2$  to  $\text{SO}_3$ , it is evident that if a simple reduction of nitrous acid took place in the Glover tower there could only be produced there 0.48 or 0.56 to 0.91 or 1.22 per cent. of sulphuric acid. It is obvious, therefore, that the nitrous acid entering the tower must be successively reduced and oxidised, in round numbers, 20 times.

Take into account the fact that in the active zone of the Glover tower there is a maximum of 0.55 of empty space, and further that the denitration all takes place in the upper half of this zone; in the smaller towers, therefore, having from 4 to 6 cubic metres of working capacity, these successive oxidations and reductions must take place in a space of from 1 to  $1\frac{1}{2}$  cubic metres, while in the larger towers, having a working capacity of from 8 to 10 cubic metres, they take place in a space of from 2 to  $2\frac{1}{2}$  cubic metres (per 1,000 kilos. of sulphur burnt in 24 hours).

Assuming that there is admitted into the burners the minimum quantity of air compatible with good working, for every kilogramme of sulphur burnt there enters the tower 7,140 litres of gas measured at  $0^\circ$  and 760 mm. and in the dry state.

The composition of this gas will be—

	Litres.
$\text{SO}_2$ .....	699.1
O .....	593.2
N .....	5,847.8
	<u>7,140.1</u>

In a tower producing 18 per cent. of the total yield, this volume of gas will be reduced to 6,951.3 litres, and in a tower producing 25 per cent. of the total yield will be reduced to 6,877.9 litres, or there will pass through the working zone of the smaller tower an average volume of 7,045 litres, and through that of the larger tower an average volume of 7,009 litres. In two towers working at these rates, it was found that the mean temperature of the gases issuing from the smaller one was  $80^\circ$  and from the other one  $95^\circ$ ; by referring to a table of the tensions of aqueous vapour, it is easy to calculate the actual volumes of the gases at these temperatures.

In the first case it is—

$$7,405 \times \frac{760}{760 - 35.5} \times (1 + 0.293) = 9,542 \text{ litres;}$$

and in the second case—

$$7,009 \times \frac{760}{760 - 43.4} \times (1 + 0.348) = 10,006 \text{ litres.}$$

The time that this volume of gas is in the working space of the Glover tower varies, therefore, from 9 to  $21\frac{1}{2}$  seconds, and consequently each period of oxidation and reduction lasts from half a second to one second.

Such a phenomenon cannot be explained solely on the ground of the affinity of nitric oxide for the oxygen of the air. The author proceeds to show that it can be explained according to his theory.

He takes the actual case of an apparatus producing in winter 19,500 kilos. of  $\text{H}_2\text{SO}_4$  per 24 hours. The Glover tower had a working space of 55 cubic metres (by working space is meant the total space occupied by the packing above the grate), with a height of 5.6 metres. This tower was fed by 62,000 litres of  $60^\circ$  B. acid from the Gay-Lussac tower, and by 10,000 litres of chamber acid of  $55^\circ$  B. It produced 4,900 kilos. of  $\text{H}_2\text{SO}_4$  in the form of  $60^\circ$  B. acid per 24 hours.

Acid entering the tower:—

62,000 litres of $60^\circ$ B. =	106,082 kilos. of $60^\circ$ B.
10,000 litres of $55^\circ$ B. =	14,426 kilos. of $60^\circ$ B.

120,508 kilos. of  $60^\circ$  B.

corresponding to—

82,850 kilos. $\text{H}_2\text{SO}_4$ .....	+ 23,232 $\text{H}_2\text{O}$
11,301 kilos. $\text{H}_2\text{SO}_4$ .....	+ 4,849 $\text{H}_2\text{O}$
<u>94,151 kilos. <math>\text{H}_2\text{SO}_4</math> .....</u>	<u>+ 28,081 <math>\text{H}_2\text{O}</math></u>

Acid leaving the tower:—

$$120,508 + \left(4,900 \times \frac{160}{78.1}\right) = 126,782 \text{ kilos. of } 60^\circ \text{ B.}$$

corresponding to—

$$100,017 \text{ kilos. } \text{H}_2\text{SO}_4 + 26,765 \text{ } \text{H}_2\text{O}.$$

There left the tower, therefore—

$$28,081 - 26,765 = 1,316 \text{ kilos. } \text{H}_2\text{O}$$

in the form of vapour. To this must be added the water introduced with the nitric acid, which was equal to 118 kilos., making a total of 1,434 kilos. of water-vapour.

This weight of vapour was held in solution by the gases. The temperature of these at the exit of the Glover tower was  $95^\circ$ . In the dry state, and measured at  $0^\circ$  and 760 mm., their volume was shown above to be 6,878 litres per kilo. of sulphur burnt. Assuming that 1 kilo. of sulphur produces 3 kilos. of  $\text{H}_2\text{SO}_4$ , the total volume of gas on a total yield of 19,500 kilos. of  $\text{H}_2\text{SO}_4$  is—

$$6,878 \times \frac{19,500}{3} = 44,708 \text{ cubic metres.}$$

The nitrous acid consumed in the tower was equivalent to 24 parts  $\text{NaNO}_3$  per 100 of sulphur. Assuming that this left the tower entirely in the state of NO, there would leave

$$0.24 \times \frac{19,500}{3} \times \frac{30}{85} = 550.6 \text{ kilos. NO.}$$

If  $V$  = the actual volume of gas leaving the tower,  $f$  = the tension of the aqueous vapour,  $h$  = the tension of NO in the mixture, these values may be found from the equations—

$$V \times \frac{f}{760} \times \frac{0.805}{1.3477} = 1,434.$$

$$V \times \frac{h}{760} \times \frac{1.3434}{1.3477} = 550.6.$$

$$V \times \frac{760 - f - h}{760} \times \frac{1}{1.3477} = 44,708.$$

whence—

$$f = 28.8 \text{ mm., } h = 6.6 \text{ mm., } V = 62,355 \text{ cubic metres.}$$

Referring to the author's table of the tension of aqueous vapour emitted by sulphuric acid, it will be seen that if the acid introduced into the tower had the same temperature as the gases, viz.,  $95^\circ$ , an aqueous vapour tension of 28.8 mm. would correspond to a strength of  $74\frac{1}{2}$  per cent.  $\text{H}_2\text{SO}_4$  = sp. gr. 1.671. If the temperature were  $85^\circ$  it would contain 71.2 per cent.  $\text{H}_2\text{SO}_4$  = sp. gr. 1.64, if the temperature were  $75^\circ$  it would contain only 66.5 per cent.  $\text{H}_2\text{SO}_4$  = sp. gr. 1.575. Such differences would produce very different working in the tower.

In the case under consideration we have—

$$550.6 \times \frac{38}{30} = 697.4 \text{ kilos.}$$

nitrous acid issuing from the tower in a volume of 44,708 cb. metres of gas measured at  $0^\circ$  and 760 mm. = 15.6 mgrm.

nitrous acid per litre of gas. Acid of sp. gr. 1·671, even at a temperature of 90° in an atmosphere containing this quantity of nitrous acid, would dissolve a very considerable quantity of the latter and carry it down to a lower stratum. There, owing to the higher temperature, the acid would be denitrated little by little, the sulphurous acid would be oxidised, and the NO produced would re-ascend to the higher stratum, become re-oxidised, fixed by the sulphuric acid, and carried down again. It is this continuous circulation of nitrous acid which explains the action of the Glover tower as a producer of sulphuric acid.

It is obvious that the more concentrated the acid introduced into the tower the larger is the zone of denitrification and the better chance the nitric oxide has of being re-oxidised, so as to be carried down again; and consequently the more acid would actually be manufactured in the Glover tower.

The author then proceeds to show that if the acid used in the tower is too dilute a too rapid reduction takes place, and the Glover tower ceases to be an important factor of production. But even if the acid used be concentrated, the result is not satisfactory if the top part of the packing is cold, as the acid will there become diluted. The cooling of the packing is produced by three causes:—

1. Too small a sectional area, in which case the acid falls in large quantities upon the first layers and cools them.
2. A too great height of packing, so that the gases get too cold before they reach the top.
3. Exposure of the tower to the wind.

With regard to the third cause, the author has found great improvement in the working of a Glover tower by shielding it from the wind.

**Reactions in the First Chamber.**—In order to prevent the lead of the chamber being too rapidly attacked, manufacturers keep the acid on the sides at between 51° and 53° B. (sp. gr. 1·540 to 1·580 = 64 per cent. to 67 per cent.  $\text{H}_2\text{SO}_4$ ). Reference to the experiments of the author on the temperatures of the chamber show that the temperature of the wall is about 75° when that of the axis is 90°. For acid of 67 per cent. at the walls with a temperature of 75°, the tension of aqueous vapour is 27 mm.; the acid in suspension in the atmosphere having necessarily the same tension as this, but being at a temperature of 90°, must consequently contain 73 per cent.  $\text{H}_2\text{SO}_4$  (57° B.). If the acid on the wall only contain 64 per cent.  $\text{H}_2\text{SO}_4$ , the tension of its aqueous vapour will be 37·4 mm., and therefore the acid in the interior will contain 71 per cent.  $\text{H}_2\text{SO}_4$  (55·7° B.). These theoretical figures agree with the result of practical tests, several instances of which the author quotes, and justify the assumption that throughout each transverse section there is equilibrium of aqueous vapour tension.

He explains the inutility of the second half of a chamber as shown in Lunge and Naef's diagram, as follows. As the gases pass from one end of the chamber to the other they become poorer in  $\text{SO}_2$ . We have seen that in the interior parts of the chamber the heat given out by the chemical reactions is not compensated for by the radiation from the walls, and in fact we find a marked elevation of temperature towards the middle of the chamber; but from this point to the end of the chamber there is no material change at the axis.

This is clearly shown by the following observations of temperature at the axis of a chamber at different distances from the fore-end:—

	0·5 m. from Top.	3·5 m. from Top.
1·5 m. from fore-end .....	° C. 77	° C. 80
11·5 " " " .....	81	86
21·5 " " " (steam jet) .....	86	91
31·5 " " " .....	83	90
42·5 " " " (steam jet) .....	84	91

In the neighbourhood of the walls the temperature is found to fall barely 2°. Owing, however, to the decrease of sulphurous acid in the gases, the production of sulphuric acid tends to decrease, and the acid which condenses on the walls is always a little weaker at the end than in the middle (about 1° B.). The tension of the aqueous vapour is consequently greater, and the acid in suspension in the interior must be weaker. It is therefore less capable of determining the oxidation of the nitric oxide, and consequently of sulphurous acid, and the fact of this taking place just when the oxidation of sulphurous acid becomes more difficult, owing to the smaller quantity present in the gases, is the explanation of Lunge and Naef's diagram.

**Influence of the Connecting Pipes.**—The author ascribes the renewed activity of sulphuric acid formation at the entrance of the second chamber not to the better mixing of the gases in the pipe, but to the cooling influence of the latter. The gasses being cooled there 20° or 30°, condensation of water takes place which dilutes the acid in suspension and suddenly liberates from it a large quantity of nitrous acid, which thereupon produces the rapid oxidation of the sulphurous acid.

**Application of the preceding Views.**—The author suggests the following apparatus:—A Glover tower capable of producing 25 per cent. of the total yield, a chamber capable of oxidising 75 per cent. of the sulphurous acid that enters it (Lunge and Naef's diagram shows that this chamber would be about a quarter the capacity of ordinary chambers); following upon this chamber, a series of cooling pipes and small towers, the latter traversed by acid of 60° B. from top to bottom, whilst the gas and steam are introduced at the bottom. Assuming that these towers have each a cubical content equal to half that of the Glover tower, he reckons that with three towers there would be produced 93·27 per cent. of the total theoretical yield with a saving of about 60 per cent. in the capacity of the apparatus used.

**Conclusions.**—The author draws the following conclusions from his investigations:—

1. The successive oxidations and reductions of the oxides of nitrogen which determine the transformation of sulphurous acid to sulphuric acid are brought about by the variations in degree of hydration of the sulphuric acid suspended in the gases.
2. In the apparatus ordinarily used these variations of hydration are brought about by changes of temperature and are in direct relation to these.
3. The working of a sulphuric acid apparatus can be advantageously modified by increasing artificially and at certain points the concentration of the acid in contact with the gases and denitrating this acid at neighbouring points so as to bring about an active circulation of the oxides of nitrogen between the neighbouring zones.
4. The application of this process on an industrial scale should permit of a decrease in the first cost of plant and assure greater regularity of working.—H. S. P.

#### *Suggestions for the Improvement of the Sulphuric Acid Process.* F. Bode. Zeits. f. angew. Chem. 1890, 11—13.

It was first pointed out by Lunge and Naef (Chem. Ind. 1884, 5; this Journal, 1884, 633), and afterwards by Schertel (Chem. Ind. 12, 80—81; this Journal, 1889, 283), that only the first half of the sulphuric acid chamber was efficient. Schertel says, "only in the first half of the first chamber does the sulphurous acid become oxidised, whilst in the second half the quantity of sulphurous acid in the gases undergoes no decrease. After passing into the second chamber a revivification of the process takes place, but dies out again as soon as the gases have passed through the first half of this chamber," and so on in the other chambers. Schertel then proposes to substitute a number of small chambers for the large systems now in use. Lunge (Zeits. f. angew. Chem. 1889, 385; this Journal, 1889, 774—775) thinks Schertel's proposal too crude, and suggests the adoption of a preliminary mixing apparatus for the gases, together with suitable means of cooling within the apparatus. Further, he proposes the use of towers or columns of perforated porcelain plates (plattenthürme) between the

chambers, in which the enfeebled reactions will again be set going.

Sorel (this Journal, 1890, 181) recommends a system of cooling tubes and towers down which 60° B. acid is allowed to percolate.

The author points out that Schertel's suggestion merely means the same thing as the subdivision of the existing length of chamber into two parts, so that each part then becomes a chamber—in other words, substituting two short chambers for one long one. The term "short" is, however, a relative one, and instead of decreasing the length we may make a short chamber by increasing the breadth. An extreme case would be that in which what is now called the length of a chamber would be considered its breadth and *vice versa*. In such a case the gases would enter at one of the long sides of a chamber and pass out at an opening in the opposite long side.

Schertel's plan involves an increased expenditure of sheet-lead, the author's a decreased expenditure. Supposing it is desired to convert a set of a total capacity of 3,240 cm., consisting, say, of three chambers each 6 × 6 × 30 m. Following Schertel's plan, and making it into six chambers, this would mean an increase of wall-surface in the ratio of 100:109. Adopting the author's plan we have: (a.) The number of chambers (three) remains unaltered, but the breadth of each is doubled; this means a decrease of wall-surface in the ratio of 100:86.4 (b.) Six chambers are made, each of 12 m. width; this means a slight increase of surface—about 4.5 per cent. If only five chambers be formed, however, the surface is the same as in the case of the original three chambers.—H. S. P.

#### *The Formation of some Fluorine Salts and their Industrial Value.* M. Netto. Zeits. f. angew. Chem. 1890, 45—46.

Sodium fluoride melted with aluminium chloride forms cryolite and sodium chloride (G. Forster, this Journal, 1888, 851); melted with sulphate of alumina, cryolite and sodium sulphate result (Winkler); with aluminium hydrate, sodium fluoride forms cryolite and sodium aluminate,  $3\text{Na}_2\text{O} \cdot \text{Al}_2\text{O}_3$  (Schuch); this, when extracted with water and treated with carbon dioxide, yields the hydrate of aluminium and sodium carbonate. Aqueous solutions of sodium fluoride and aluminium sulphate when mixed together form a fluorine aluminium hydrate, and this, when fused with sodium fluoride, also yields cryolite.

Magnesium salts behave in a similar manner to aluminium salts towards sodium fluoride. Aqueous solutions of sodium fluoride and magnesium sulphate give an amorphous precipitate of fluorine magnesium hydrate; when boiled with water and magnesite the analogue of cryolite ( $3\text{NaF} \cdot \text{AlF}_6$ ) is formed— $3\text{NaF} \cdot \text{Mg}_2\text{F}_6$  (Tissier). Magnesium sulphate melted with sodium fluoride forms magnesium cryolite,  $6\text{NaF} \cdot \text{Mg}_3\text{F}_6$ —a crystalline powder—the crystalloids being regular cubes. This body behaves like cryolite towards acids; treated with caustic soda magnesium hydrate is separated whilst cryolite dissolves completely.

In commenting on the possibility of replacing natural cryolite by artificial cryolite or by this magnesium cryolite, the author points out the advantage of the last when compared with the artificial cryolite in point of price, owing to the magnesium salts being cheaper than those of aluminium; further, that a cheap method of preparation of sodium fluoride is what is really required to make either process a success.

The direct preparation of cryolite according to either of the following equations is possible, but the reaction is incomplete and the mass gets thicker and thicker as the quantity of calcium carbonate formed increases:—

#### *The Soda Industry in the Year 1889.* A. Hasenclever. Chem. Ind. 12, 431—436.

BITTER competition among German manufacturers engaged in the soda industry has made business profitless to all. Repeated attempts to form a combination have failed through the pretensions claims of individual producers. The fact that in 1888 the exports, reckoned on 100 per cent. carbonate of soda, exceeded the imports by 18,000 tons is no criterion of the general sound development of the industry, and profitable working has occurred in only exceptional cases. A sound basis for a lasting export trade in soda is lacking in Germany. A superficial comparison of the more favourable conditions that obtain in England, with her extended water highways and over-sea communications, shows the great disadvantages under which Germans have to compete in all industries which depend upon the bringing of various raw materials of small value to one point. The low railway tariff in England, arising from the competition of private railway companies, gives a great advantage to English makers, whilst the German State railways maintain a high tariff. Were there cheap carriage of fuel alone in Germany, great benefit would follow, as industries would then be carried on more generally throughout the land instead of being concentrated in the vicinity of the coal-fields.

The soda industry has grown in England, as it has in Germany, from year to year, during the last decade. In England there were used in this manufacture 568,512 tons of salt in 1878, and 781,348 tons in 1888. The increased production in England is entirely due to the manufacture of ammonia-soda. Many of the smaller Leblanc-soda makers have stopped their works, whilst the larger ones have gone on as before, and have reaped a moderate profit by the aid of a combination to limit the production of bleaching powder. The production of ammonia-soda in England has been limited to about one-fifth of the total make of soda, and the price obtained has enabled the firm of Brunner, Mond, and Co., to divide a dividend of 25 per cent.

In France, where, owing to trade combination and the high import duties, the price of soda has been the highest for many years, there seems to be a falling off in demand. The Leblanc-soda makers have suffered most, as the ammonia-soda makers are guaranteed the sale of a fixed amount.

In Austria, a combination among soda manufacturers has reduced the yearly make of all the works, and there would seem to be in that country a prospect of future stability were it not that German competition appears to preclude any material rise in price.

If, under such unfavourable conditions, some makers have carried on their works at a profit, this has been due either to an increase in the value of by-products, or to the working of other branches of manufacture which permit of being carried on in connexion with the soda process.

After drawing attention to Mond's method of recovering ammonia and tar from fuel as carried out at Northwich (this Journal, 1889, 505), the author goes on to describe other processes that have been adopted in connexion with soda works.

The "Chemische Fabrik Rhebania" has been making sulphuric acid from zinc blende, in connexion with spelter works at Stolberg, Oberhausen, Hamborn, Bensberg, and Dortmund. Ten years ago 12,000 tons of sulphuric acid, 60° B., were made, and in 1888 the quantity reached 51,010 tons.

W. Grillo has worked out a process for making liquid sulphurous acid from blende, and at Lipine, in 1888, 1,141 tons of liquid sulphurous acid were thus made and found a ready sale enclosed in iron vessels; but in Silesia the process has not been profitable.

Since the consumption of sulphuric acid increases year by year, the author thinks that both in Silesia and Belgium, in the course of time, all zinc works will utilise the gases from blende roasters. One cause for an increased demand for sulphuric acid will be the increased manufacture of sulphate of ammonia from the ammonia recovered from fuel and from coke-ovens. In Silesia 120 new coke-ovens adapted to this purpose were erected in 1889.

Efforts on the part of ammonia-soda makers to combine the manufacture of chlorine with the ammonia-soda process have so far led to no practical results. In view of the present value of hydrochloric acid, the author has been of opinion that up to the present day in Germany, the Leblanc-soda manufacturer has had an advantage over the ammonia-soda maker, but owing to the enormous rise in the price of fuel and the fact that twice as much fuel is used in the Leblanc process as in the ammonia-soda process for a given weight of soda, he thinks that in 1890 the Leblanc-soda maker will be at a disadvantage. The increased price of salt will affect the old process more unfavourably than the new, since the ammonia-soda makers usually have their own brine. The value of bleaching powder and hydrochloric acid is also likely to fall, in view of the manufacture of hydrochloric acid and chlorine from magnesium chloride, the introduction of electrolytic methods of bleaching and the making of chlorine by Campbell and Boyd's process now being worked out at the North British Alkali Works in Glasgow (Eng. Pats. 10,187, July 13, 1888, and 18,056, December 11, 1888; this Journal 1889, 983).

Reference is next made to Chance's sulphur-recovery process (this Journal 1888, 162) and to the patents of Gossage, Rawes (Eng. Pat. 1393, March 22, 1882; this Journal, 1882, 454), and Opl (Ger. Pat. 23,142, October 8, 1882; this Journal, 1882, 452), and the author then proceeds to describe experiments that he has carried out on a manufacturing scale with the v. Miller and Opl process for recovering sulphur or sulphuretted hydrogen from soda-waste.

According to the method of von Miller and Opl (Eng. Pat. 2334, January 29, 1884; this Journal, 1884, 373, 393, 551) calcium sulphhydrate is decomposed by steam instead of by carbonic acid, as in Chance's patent.

The following considerations among others induced the author to attempt to carry out in a large scale the v. Miller and Opl process in preference to that of Chance:—1. By the v. Miller and Opl process, pure sulphuretted hydrogen is formed instead of a gas containing 33 per cent.  $H_2S$  as in Chance's process. 2. Calcium hydrate is formed in the former process, for which a use can be more easily found than for the calcium carbonate formed in the latter process. 3. The employment of lime kilns and blowing engines is avoided, and the employment of boilers for generating steam is a cheaper plan of working.

The heat required to carry out the reaction was estimated theoretically as follows:—

That is to say, for the recovery of every 64 kilos. of sulphur from  $\text{CaS}_2\text{H}_2$ , 25,160 heat units must be supplied to complete the reaction, or for every 100 kilos. of S, 40,000 heat units are needed. Supposing that 1 kilo. of coal yields 5,000 heat units, then 8 kilos. of coal would be required to recover 100 kilos. of S. This amount left a wide margin for practical working. The apparatus consisted of horizontal wrought-iron cylinders, fitted with suitable appliances for agitating their contents. The accompanying Figure shows the arrangement.

The soda-waste is mixed with water in the mixing apparatus I., and passes thence into the cylinders II. and III., where it is subjected to the action of sulphuretted hydrogen, whereby calcium sulphhydrate is formed. The cylinder IV. is surrounded by a steam-jacket. In this cylinder the sulphhydrate is warmed up and then passes into the three lower cylinders V., VI., VII., where it is decomposed by steam. The steam enters the lowest cylinder VII. first, and then passes through into the two upper ones. The evolved  $H_2S$ , together with the excess of steam, then leave V. by a pipe and pass into the jacket round cylinder IV., where they warm up the calcium sulphhydrate contained in the cylinder. From the jacket the  $H_2S$  and uncondensed steam next pass into a condenser VIII. cooled with water, where the rest of the steam condenses, and the  $H_2S$  is then passed into the cylinders III. and II. Here half the  $H_2S$  is used to form

calcium sulphhydrate,  $\text{CaS} + \text{H}_2\text{S} = \text{CaS}_2\text{H}_2$ ; the other half passes from the apparatus II. to be made further use of:—

The experiments that have been carried out show that the conversion of all the  $\text{CaS}$  into  $\text{CaS}_2\text{H}_2$  is easily effected in the absorption cylinders, and that heat is evolved in the reaction, so that it is necessary to cool these cylinders with water. A liquor of  $28^\circ \text{B.}$  is easily obtained containing 212 grms. of sulphur per litre. The decomposition of the sulphhydrate by steam only takes place rapidly enough, however, when the solution is concentrated. The further the decomposition has been carried the slower it goes on. The author intends to publish a more detailed account of the experiments later. They have indeed shown that it is possible to recover nearly all the sulphur as  $H_2S$  by this method, but the quantity of coal used in generating the necessary quantity of steam was 90 times the theoretical quantity. A modified apparatus reduced this amount considerably, but nevertheless the reaction was too slow. He does not yet consider the experiments as completed, but does not think the future prospect is promising for the process.

The fact that by this process pure  $H_2S$  is obtained is on closer consideration not a great advantage, except that gasometers are not needed for collecting it. This is obvious from the fact that the gas from Chance's process, which contains 33 per cent.  $H_2S$ , is quite suitable for burning to make sulphuric acid, and contains only about the same quantity of air as would be consumed in burning pure  $H_2S$ .

The question of using the  $H_2S$  for making S is one that must be considered, not on the basis of present prices, but in view of a considerable fall in price, due to the competition which would ensue were all Leblanc-soda makers to recover the sulphur from their waste. England alone would produce 142,000 tons, whereas her import of sulphur is now only 32,000 tons.

The cost of plant for working up the waste in a works using 1,000 tons of salt per week is reckoned in England at 1,000,000 marks. In that country the calcium carbonate produced (which is too fine for use in making soda) can be disposed of for cement-making more easily than in Germany, owing to the higher cost of carriage in the latter country. Moreover, English works are generally very limited in space, and have to pay a good deal to get the waste removed. Finally, taking into account the fact that, whilst in England to make 100 kilos. of S, 0.38 marks are reckoned for coal, whilst Germans have to pay twice that sum, it can easily be understood why German soda-makers are chary of setting up sulphur-recovery plant, whilst on the other hand in England there are three works already working the process, and many others engaged in erecting the necessary plant.—H. S. P.

*On the Proportion of Water to Hydrochloric Acid formed by igniting Mixtures of Hydrogen, Oxygen, and Chlorine.* P. Hautefeuille and J. Margottet. Compt. Rend. 109, 641—643.

This research is regarded as preliminary to an investigation of the decomposition of water by means of heat in the presence of chlorine and carbon monoxide.

In a first series of experiments, a known volume of chlorine was added to a given amount of gas obtained by the electrolysis of water. In a second series, a known volume of oxygen was added to the elements of hydrochloric acid. The mixtures were exploded in a thick glass tube containing about 80 cc. by means of a spark. The apparatus is not described in detail.

The pressures of the gases and the amount of chlorine before and after the explosion were determined, the residual chlorine being estimated by means of a solution of sodium arsenite.

These data enable one to deduce from them the amounts of water and of hydrochloric acid formed.

Let  $h$  be the pressure of the hydrogen,  $H$  the pressure of the chlorine, these being introduced into the eudiometer at the same temperature.

$p$  the weight of hydrogen,  $P$  the weight of chlorine introduced.

$p^1$  the weight of hydrogen which unites with chlorine during the experiment.

$p^1$  the weight of chlorine which remains uncombined.

We have—

$$P = p \times \frac{0.069}{2.44} \times \frac{h}{H}.$$

#### SERIES I.—SYNTHESIS OF WATER IN THE PRESENCE OF CHLORINE.

Composition of the gaseous mixture.	Vols. of O	$\frac{1}{2}$	$\frac{1}{4}$	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$
	Vols. of H	1	1	1	1	1	1	1	1	1
	Vols. of Cl	$\frac{1}{2}$	$\frac{1}{4}$	$\frac{1}{2}$	1	$\frac{3}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	2
Value of $\frac{p-p^1}{p^1}$ .....		$\frac{5}{4}$	$\frac{1}{1.8}$ to $\frac{1}{2.9}$	$\frac{1}{2.3}$ to $\frac{1}{2.5}$	$\frac{1}{3.8}$ to $\frac{1}{4.3}$	$\frac{1}{5.2}$ to $\frac{1}{5.7}$	$\frac{1}{9.2}$ to $\frac{1}{11.2}$	$\frac{1}{20}$	$\frac{1}{40}$	0

(1.) As soon as the volume of chlorine is greater than half the volume of hydrogen contained in the electrolytic gas,  $\frac{p-p^1}{p^1}$  is less than unity, and diminishes rapidly with the increase in the proportion of chlorine, so that when

Since  $p^1$  is the weight of hydrogen which unites with chlorine, it is evident that  $p - p^1$  = the weight of hydrogen which unites with oxygen and

$\frac{p-p^1}{p^1} = \frac{\text{number of half molecules of water}}{\text{number of molecules of hydrochloric acid}}$  formed during the experiment.

The authors found that  $\frac{p-p^1}{p^1}$  does not vary with the pressure between the limits of  $\frac{1}{3}$  and  $\frac{2}{3}$  of an atmosphere, nor with the nature of the spark.

#### SERIES II.—SYNTHESIS OF HYDROCHLORIC ACID IN THE PRESENCE OF OXYGEN.

Composition of mixture	Vol. of Cl .....	1	1	1	1	1	1	1
	Vol. of H .....	1	1	1	1	1	1	1
	Vol. of O .....	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	3
Value of $\frac{p-p^1}{p^1}$ .....		$\frac{1}{7.2}$	$\frac{1}{4.3}$ to $\frac{1}{4.7}$	$\frac{1}{3.8}$ to $\frac{1}{4.3}$	$\frac{1}{3.4}$	$\frac{1}{3.1}$ to $\frac{1}{3.3}$	$\frac{1}{3.2}$	$\frac{1}{3.2}$

The ratio  $\frac{p-p^1}{p^1}$  is always less than unity, and varies but little when the ratio, by volume, of oxygen to hydrogen present is increased from  $\frac{1}{2}$  to 3.

The results may be put in the form of equations, e.g.:—

The temperatures to which these states of equilibrium correspond cannot be determined directly. The authors intend to estimate them by means of data furnished by Berthelot and Vieille, and also by some further experiments.

—P. J. H.

*On the Distribution of Hydrogen between Chlorine and Oxygen.* H. Le Chatelier. *Compt. Rend.* **109**, 664–667.

THE experiments of Hauteville and Margottet (preceding abstract) on the distribution of hydrogen in presence of chlorine and oxygen supply important information respecting the general laws of chemical equilibrium. The author has been engaged upon similar researches (undertaken with the intention of applying the results to the Deacon process for the manufacture of chlorine), and points out how the value of the coefficients of distribution can be determined by calculation.

The formula for equilibrium in the case of a mixture of oxygen, chlorine, water, and HCl is—

$$\text{Loge } \frac{p(\text{O}_2) \times p^4(\text{HCl})}{p^{1/2}(\text{Cl}_2) \times p^{1/2}(\text{H}_2\text{O}_2)} + 500 \int \frac{LdT}{T^2} = \text{const.}$$

$L$  is the heat of reaction of 1 molecule of oxygen with 4 molecules of HCl; its value is 28 at ordinary temperatures, and does not vary much up to 1,000°. The value of the constant depends upon the composition of the mixture in equilibrium; its normal value in the Deacon process is 15. In order to apply the formula it is necessary to express the pressures as functions of the number of molecules of each substance.

If we denote these as follows:—

Substance .....	$\text{H}_2$	$\text{O}_2$	$\text{Cl}_2$	$\text{H}_2\text{O}_2$	HCl	$\text{N}_2$
Number of molecules	1	$n$	$n'$	$x$	$2(1-x)$	$N$

and further denote the pressure (in atmospheres) of the mixture by  $P$ , the formula becomes—

$$\text{Loge } P + \text{loge } \frac{16(2n-x)(1-x)^4}{(2n+2n'+2N+2-x)(n'-1+x)^2x^2} + \frac{1,400}{T} = 15.$$

This formula applies up to 1,000°, but is not rigorously correct at higher temperatures when the dissociation of the chlorine molecule becomes appreciable. The hygrometric state, which is of importance, has not been indicated in the experiments of Hauteville and Margottet. We must therefore assume that the gases were saturated with water-vapour at 15°, i.e., that they contained 2 per cent. by volume. The temperature of the mixture corresponding to the state of equilibrium has not been (and cannot be) determined. It depends upon the relative rapidities of the chemical reactions and the cooling effect. The former increases rapidly with the temperature, being practically zero at 500° and only acquiring a noticeable value above 800°. We can only suppose that the temperature in question is higher than 1,000° and lower than 2,000°.

*Influence of Temperature.*—The proportion of water produced ought to decrease as the temperature increases. The following table, calculated from the formula, gives the number  $x$  of molecules of water produced per molecule of hydrogen in a mixture containing equivalent proportions at the atmospheric pressure—

$t$ .....	0°	300°	400°	650°	1,120°
$x$ .....	0.098	0.90	0.80	0.50	0.20

The oxidation of HCl should therefore be practically complete at ordinary temperatures. This has already been proved by M. Berthelot.

**Influence of Pressure.**—The formula indicates a diminution in the proportion of water when the pressure diminishes. This diminution is small, because the change of volume accompanying the reaction is itself small. It must however occur, if the molecular volumes assigned to the various substances are correct, for it follows directly from the second law of thermodynamics. On the other hand the experiments of MM. Hautefeuille and Margottet show that change of pressure produces no effect. This shows that the molecule of chlorine is, under the given conditions,

partially dissociated; if it were completely dissociated the diminution of pressure would, on the contrary, increase the proportion of water produced.

**Influence of the Relative Proportion of Elements present.**—This is the most interesting point, for it enables us to test the correctness of the formula. The following table gives the calculated proportions of water produced from a mixture containing equivalent proportions, and also those obtained by MM. Hautefeuille and Margottet, allowing for 2 per cent. of water-vapour by volume:—

Cl <sub>2</sub>	1	1.25	1.50	2	1	1	1	0.5
H <sub>2</sub>								
O <sub>2</sub>	0.5	0.5	0.5	0.5	0.25	1.25	3	0.5
H <sub>2</sub>								
H <sub>2</sub> O <sub>2</sub> {calculated.....}	0.258 {	0.15	0.07	0.06	0.19	0.25	0.27	0.63
H <sub>2</sub> {observed.....}		0.148	0.08	0.07	0.215	0.275	0.31	0.58

The agreement between the calculated and observed values is thus seen to be most satisfactory; it is even better than could have been expected, inasmuch as no allowance is made for possible dissociation of chlorine. The action of the excess of chlorine or oxygen depends, therefore, solely upon the relative volumes of the bodies present, and is in no way dependent upon their special chemical properties, for these do not enter at all into the formula.

The distribution of oxygen between carbon monoxide and hydrogen may be similarly represented—

$$\text{Log} \epsilon \frac{p(\text{C}_2\text{O}_2) \times p'(\text{H}_2\text{O}_2)}{p''(\text{H}_2) \times p'''(\text{C}_2\text{O}_4)} + 500 \int \frac{L dT}{T^2} = \text{const.}$$

or, neglecting the variation of L with temperature, and using the following notation for a mixture containing a semi-molecule of displaceable oxygen—

Substance..... CO<sub>2</sub> H<sub>2</sub> H<sub>2</sub>O<sub>2</sub> C<sub>2</sub>O<sub>4</sub>  
Number of molecules  $n$   $n'$   $x$   $1-x$ .

$$\text{Log} \epsilon \frac{(n-1+x)x}{(n'-x)(1-x)} + \frac{5000}{T} = \text{const.}$$

In this case it will be observed that the state of equilibrium is strictly independent of the pressure.—D. E. J.

#### *The Preparation and Properties of Anhydrous Platinum Difluoride.* H. Moissan. Compt. Rend. 109, 807—809.

This body is prepared by passing fluorine over a bundle of platinum wires heated to about 500°—600° C., and placed in a stout platinum tube. If no hydrofluoric acid be present no reaction takes place at all up to 100° C. At ordinary temperatures platinum itself is entirely unacted upon by fluorine. A mixture of fluorine and hydrofluoric acid, however, is more energetic in its action than fluorine alone. The fluoride is obtained as a fused mass of a deep reddish colour or as small yellow crystals much resembling those of the dichloride. It is exceedingly hygroscopic and its reactions with water are very characteristic. If placed in a little water it dissolves, but the solution becomes hot and the hydrated oxide is then precipitated. With a comparatively large quantity of cold water the decomposition is retarded, but on warming the salt is at once decomposed. Its peculiar behaviour with water explains the fact long ago observed that the anhydrous difluoride cannot be obtained in the wet way, for, as seen, it rapidly decomposes water to form hydrofluoric acid and the brownish-yellow precipitate recalls to mind Frémy's hydrated dioxide PtO<sub>2</sub>.H<sub>2</sub>O<sub>2</sub>. When raised to a bright red heat the fluoride readily splits up into fluorine and platinum, the latter presenting a distinctly crystalline appearance.

The salt was analysed by dissolving a portion in a large quantity of water, then pouring off from any slight insoluble residue and boiling the clear solution. On drying the precipitate and igniting, the weight of platinum thus obtained gave the formula PtF<sub>2</sub> for the new compound.—S. G. R.

#### *Further Researches on the Preparation and on the Density of Fluorine.* H. Moissan. Compt. Rend. 109, 861—864.

THE fluorine was obtained by the electrolysis of pure hydrofluoric acid, in quantities of about 100 cc. at a time, contained in the platinum apparatus similar to the one formerly described but of a capacity of about 160 cc. Lest the fluorine should carry over with it any traces of hydrofluoric acid, the products of electrolysis were passed through a platinum spiral placed in a bath of methyl chloride giving a temperature of about -50° C. or 70° C. below the boiling point of the acid. The gas then passed over sodium fluoride and, being considered pure, was led to the apparatus shown in the Figure.

This was a platinum flask of a capacity of about 100 cc. and weighing about 70 grms., and closed by a rounded perforated stopper accurately fitted to its seat and serving also as a stopcock. The flask was first filled with pure dry nitrogen and this in turn displaced by the fluorine which was passed in by a platinum tube fitting into A. After that silicon inflamed readily in the issuing gas the current was still continued for five minutes. The stopper was then turned round on itself and the plug being introduced into the tube A, all connexion with the exterior was cut off. The flask was then weighed on a balance turning readily with 0.0005 gm. and its capacity was also determined. From these data the density of fluorine was deduced as (1) 1.262; (2) 1.265; (3) 1.270, the figure adopted being 1.265. The theoretical density of fluorine is  $0.06927 \times 19 = 1.316$ . As was the case with phosphorus trifluoride the observed density is rather low, hence it seems possible that the accepted atomic weight of fluorine, namely 19, may be rather too high.—S. G. R.

*The Colour and Spectrum of Fluorine.* H. Moissan.  
Compt. Rend. 109, 937—940.

By analogy it was considered likely that fluorine would possess very little if any colour, since it stands first in the halogen family and is followed by chlorine, possessed of no great depth of colour in comparison with the highly-coloured bromine and still more highly-coloured iodine. A tabular apparatus of platinum was used for the observation, and care was taken that it was perfectly dry, since water is speedily decomposed by fluorine. On looking through a depth of 0.5 metre of fluorine, it was observed that the gas possesses a greenish-yellow colour much more faint than that of chlorine regarded through a tube of similar depth, and being besides a tint more closely approaching yellow than the greenish-yellow tint of chlorine. Examined through a depth of 1 metre, fluorine was not observed to possess any absorption bands. The following singular observation was made. When the platinum apparatus was filled with fluorine, a very small quantity of water was added, which immediately decomposed with formation of hydrofluoric acid and ozone. This latter gas was produced in a state of such concentration that the whole of the tube assumed the indigo-blue tint observed in ozone of Hautefeuille and Chapuis. After a few minutes, owing to the temperature of the laboratory, the ozone was partly destroyed and the colour reduced; it thus gradually faded and at length disappeared. The spectrum of fluorine was also determined, and a large number of bands, upwards of 13, all in the red part of the spectrum, were found.

*A New Process for the Utilisation of Atmospheric Oxygen and the Compounds upon which the Process is Based.*  
G. Kassner. Dingl. Polyt. J. 274, 136—142; 183—190; 226—231; 270—276.

*Preparation and Properties of Compounds Used.*—

The author found in 1884, when barium manganate was boiled with oxidisable bodies in aqueous solution it parted with its oxygen to these and was converted into a brown substance of the formula  $MnO_3Ba$ , and that this on heating in air took up oxygen and was reconverted to barium manganate. Several drawbacks attended its use; amongst others, in presence of water barium hydrate was formed which rapidly absorbed carbonic acid, and so an increasing amount of barium carbonate was contained. The regeneration, moreover, was very slow.

The author working on the subject has produced three new compounds, and describes their preparation, properties, commercial application, and chemical relationship.

*Barium Plumbate*,  $Ba_2PbO_4$ .—Barium hydrate and lead oxide were heated in a porcelain crucible over a Bunsen flame; a deep black substance was obtained. Dilute hydrochloric acid added to a portion caused effervescence as of carbonic acid; there was a strong odour of chlorine, and a yellow-green solution remained. Dilute nitric acid separated a brown powder. Sulphuric acid was without action until oxalic acid was added, when barium and lead sulphates were formed and carbon dioxide evolved. When oxalic acid was used with nitric acid a clear solution of the respective nitrates was obtained.

By mixing one equivalent of lead oxide and one equivalent of barium carbonate and heating as before, a glassy substance was produced, the colour deepening until quite black. It was powdered, and on testing showed by action of acids that carbonic acid still remained, that the whole of the lead oxide has not been converted into the dioxide, and that all the displaceable oxygen could not be obtained. The presence of lead oxide was proved by adding nitric acid and testing with sulphuretted hydrogen. The displaceable oxygen was determined by mixing three parts of the product with one part of pure oxalic acid and warming with dilute nitric acid till evolution of carbonic acid ceased, when the excess of oxalic acid was determined by titrating back with potassium permanganate,  $H_2C_2O_4 + 2H_2O + O = 2CO_2 + 3H_2O$ . Nitric acid is preferable for the determination, sulphuric acid causes separation of the sulphates, and acetic acid is unreliable.

The displaceable oxygen was found by two tests as 2.32 and 2.59 per cent.

The true barium plumbate was obtained by heating two equivalents of barium carbonate and one of lead oxide. The product was deep black, and contained only slight traces of carbonic acid and lead oxide. The displaceable oxygen was found to be 2.86; theoretically it should have been 2.94. Hypothesis points to a *plumbic acid*,  $H_4PbO_6$ , the anhydride being  $PbO_3$ .

*Strontium plumbate*,  $Sr_2PbO_4$ .—Two equivalents of strontium carbonate and one equivalent of lead oxide treated in a similar way gave a deep-brown chocolate-coloured compound showing the same reactions.

*Calcium plumbate*,  $Ca_2PbO_4$ .—This was made by heating two equivalents of calcium carbonate and one of lead oxide. A lesser heat was required than in case of the other two, and the conversion was effected in about five minutes, over the Bunsen flame. The compound was of a yellowish-red or flesh colour. The abundance and cheapness of calcium carbonate should render this the cheapest of the three compounds.

The properties of the three plumbates were similar, and all were insoluble in water. Examined microscopically, the last-mentioned was seen as an aggregate of yellowish crystals. On treatment with sodium bicarbonate, opaque brownish-black masses ( $PbO_2$ ), having between them colourless crystals ( $CaCO_3$ ), were obtained. The action of acids is similar on all three; nitric acid forms the brown lead dioxide and a nitrate of the alkaline earth. Dilute sulphuric acid gives also lead dioxide and a sulphate of the alkaline earth, though strong acid forms both sulphates. Dilute acetic acid has no action in the cold; on heating, dioxide and the acetate are formed. Hydrochloric acid dissolves them to a yellow-green liquid. To obtain a clear solution, nitric or acetic acids may be used with oxalic acid, or, preferably, hydrogen peroxide.

Carbonic acid or bicarbonates produce carbonates of the alkaline earths and lead dioxide. Sodium bicarbonate acts better than the potassium salt.

The author found that 350 grms. of calcium plumbate and 400 grms. of potassium bicarbonate in a little water, heated on the water-bath to the boiling point, gave a clear brown liquid deepening to black. The heavy powder, a mixture of lead dioxide and the corresponding carbonate, settled to the bottom, and on being dried and ignited formed again the plumbate. The soluble alkaline salts are easily removed by decanting and washing, and the alkaline carbonate can be obtained as a by-product.

Water alone, at a temperature of 150 °C., under increased pressure, caused formation of the dioxide and the corresponding alkaline hydrate. Ammonium mono- and bicarbonates gave ammonia, carbonates of the alkaline earths and lead dioxide. Ammonium nitrate and acetate gave ammonia, lead dioxide, and the respective salts of the alkaline earths.

*The Technical Application of these Compounds.*—*Calcium plumbate* is most to be preferred, being not only the easiest and cheapest to produce, but because it contains proportionately the highest percentage of displaceable oxygen, viz., 4.56 per cent. It may be used directly, as in the glass industry, for production of lead and lime glass.

Its widest application is, however, indirectly by decomposition and formation of lead dioxide. This can be accomplished, as already noted, in many ways, e.g., by water or steam under increased pressure, by carbon dioxide, mono- or bicarbonates, ammonium salts, or, lastly, by strong acids, such as acetic, nitric, sulphuric, &c.

The oxidation of potassium ferrocyanide (yellow prussiate) to potassium ferricyanide (red prussiate) is rapidly and completely accomplished by means of *calcium plumbate* and carbon dioxide.

In the presence of free caustic alkali the reaction is not complete, and excess of free alkali causes the re-formation of lead dioxide. The process is, however, cheaper than

that by means of chlorine, for the more valuable potassium carbonate is obtained instead of the chloride. Then the insoluble residue is easily separated, washed, and by subjection to a red heat in presence of air, *calcium plumbate* is regenerated.

Potassium ferrieyanide with caustic alkali is known as an excellent oxidising agent, readily oxidising lead oxide to the dioxide, chromic hydroxide to chromic acid, and manganese sesquioxide to manganese dioxide. It has recently received wide application in organic chemistry; such a solution bleaches vegetable fibre as strongly and quickly as hydrogen peroxide (compare this Journal, 1890, 108). The price has hitherto been an obstacle. This objection is now removed, because by simply boiling the reduced solution with the decomposed plumbate, and introduction of carbon dioxide, ferrieyanide is regenerated, and can thus be used again and again.

For the production of oxygen on the large scale the author recommends treating the plumbate with sodium bicarbonate, decanting off the soluble alkali, washing the insoluble residue, pressing into lumps, and drying these in the generating apparatus with superheated steam; as soon as dry, the steam is stopped, and, all air having thus been expelled, heat is applied, when the oxygen is freely given off.

The application of the barium and strontium plumbates is limited on account of the greater cost, the stronger heat required in formation, and the proportionately less amount of displaceable oxygen contained.

Although in the carefully prepared plumbates the lead oxide is entirely converted to plumbic acid, yet this is not so on the large scale, and therefore the alkali obtained (as a by-product) may contain lead in solution. The presence of so poisonous a substance in a compound having such wide applications is highly obnoxious, and care must be taken to eliminate it. This, however, is easily accomplished by means of hydrogen sulphide or any soluble sulphide with which the solution should always be tested. Barium or strontium hydrates should be treated with their respective sulphides. Another method is by electrolysis, when the insoluble dioxide is readily deposited on the anode.

The author contrasts his process with the older methods of Boussingault, of Weldon, and that of Brin's Oxygen Company.

He contends that barium dioxide becomes gradually more or less inert from formation of barium carbonate, and that it requires an extremely high heat to expel the oxygen. That by means of calcium plumbate pure oxygen is obtained; that the plumbate continues unaltered—that is the  $\text{CaCO}_3$  and  $\text{PbO}$  remain in same proportions—and that the much lower heat at which oxygen is given off would mean the use of considerably less fuel. Further, it has a higher specific heat, and although it is heavier in proportion, yet a greater percentage of oxygen is obtained by use of calcium plumbate, while there is the production as a by-product of the alkaline carbonate.

For the much-spoken-of production of chlorine from magnesium chloride, the following simple process is applicable: (1) mixing with the magnesium salt; (2) drying to expel the water of crystallisation; (3) granulating and sifting the hard mass; (4) heating it at a high temperature; (5) collecting or absorbing the chlorine given off.

The author also shows the superiority of the plumbates to the barium manganate before described.

#### *Chemical Relations of the New Bodies.*—

Frémy (Ann. Chim. Phys. 12, 409) prepared a compound by mixing lead oxide and potassium hydrate in a little water and crystallising over sulphuric acid. It was obtained in colourless crystals of composition  $\text{K}_2\text{PbO}_3 + \text{H}_2\text{O}$ . Again, W. Crum (Ann. 55, 212) prepared an almost colourless compound of calcium and lead dioxide by mixing lead nitrate, milk of lime, and calcium chloride solution and heating for some time at 160° F. The formula assigned was  $(\text{CaO}_2)\text{PbO}_2$ .

There would seem to be two hypothetical acids—

*Ortho-plumbic acid*,  $\text{Pb}(\text{OH})_4$

*Meta-plumbic acid*,  $\text{PbO}(\text{OH})_2$

The above bodies,  $\text{Ca}_2\text{PbO}_4$ ,  $\text{Sr}_2\text{PbO}_4$ , and  $\text{Ba}_2\text{PbO}_4$  would thus be *ortho-plumbates*. Red lead might be  $\text{Pb}_2(\text{PbO}_3)$  (see this Journal, 1889, 468).

The *meta-plumbate* being the  $\text{K}_2\text{PbO}_3$  prepared by Frémy, and also by Geuther (Annalen, 219, 68 and 69)—the latter by passing oxygen into a solution of oxide of lead in fused potassium hydrate—the sesqui-oxide may be written  $\text{Pb}(\text{PbO}_3)$ . The author concludes by pointing out that  $\text{PbO}_2$  thus acts similar to  $\text{SnO}_2$  and  $\text{CO}_2$ , and indicating the correspondence in the periodic system of carbon, silicon, zinc and lead.—D. A. S.

#### PATENTS.

*Improvements in the Treatment of Gases and Recovering of Sulphur from Sulphuretted Hydrogen evolved in various Manufacturing Processes.* J. Barrow, Manchester. Eng. Pat. 17,528, December 1, 1888. 8d.

THE gases are deprived of sulphuretted hydrogen by treatment in a scrubber with a solution of perchloride of iron or manganese or both. The precipitated sulphur is collected by settling and filtration. The reduced solutions are regenerated by treatment with peroxides of iron or manganese or with heated air. Plant for conducting the process is described.—G. H. B.

*Improvements in the Manufacture of Chlorine and Chloride of Lime and in Apparatus therefor.* Solvay and Co., Brussels, Belgium. Eng. Pat. 18,574, December 19, 1888. 6d.

A MODIFICATION of a process embodied in several previous patents for the production of chlorine from calcium chloride by heating it with siliceous and aluminous materials. When clay is employed it is found desirable to calcine and powder it before admixture with calcium chloride, in order to drive off combined water, which, if present, would favour the production of hydrochloric acid rather than of chlorine in the subsequent reaction. Hitherto the furnacing of the mixture has been conducted in retorts heated externally, in order to avoid contact with combustible gases containing carbonic oxide, which has a great tendency to combine with the chlorine to form carbonyl chloride, from which chlorine cannot be again recovered in its active form. The amount of fuel required by this method of heating in closed retorts is obviously very considerable, and the chief object of the present patent is to provide a method of direct heating in which the formation of carbonyl chloride shall be reduced to insignificant proportions. To this end the decomposition is effected in a high tower of thick masonry filled with the material to be treated. Gases from a coke gasifier or gas generator are introduced through a ring of short branch pipes situated near the middle of the tower, whilst air is passed in at the bottom. The cold air becomes heated in its passage through the descending hot material until it meets with the generator gas, which is completely burnt in a short space above the supply pipes, termed the zone of combustion. Above this is the zone of decomposition, in which the hot gases containing an excess of air act on the descending material and produce an evolution of chlorine. The upper layers of material serve to abstract the heat of the gases in their passage through it. The tower thus serves as a regenerative element, cool gases leaving the top, whilst the exhausted material arrives cold at the bottom. The chlorine produced in this manner being contaminated with a considerable proportion of carbonic acid, is not suitable for the production of chloride of lime by the ordinary method. The gases are therefore passed into a solution of lime which absorbs all the chlorine, but only a part of the carbonic acid, and this part precipitates from the solution as carbonate of lime. The solution of chloride of lime is then decomposed by the hydrochloric acid which is unavoidably produced in small quantities in the principal reaction, and which is condensed from the chlorine simultaneously produced. Concentrated chlorine gas is thus obtained, which is then directed either upon lime in the ordinary way, or upon imperfect chloride of lime obtained with poor chlorine, and which may then be brought to the desired strength. The dilute chlorine mixed with carbonic acid may also be employed in the manufacture

of chlorates. This process and apparatus are not limited solely to the decomposition of calcium chloride, but are applicable also to the decomposition of magnesium chloride, and of chlorides generally by the dry process. (This Journal, 1885, 345 and 533; 1886, 451; 1887, 661.)—G. H. B.

*Improvements in or relating to the Manufacture of White Lead.* H. B. Condy, Battersea. Eng. Pat. 18,705, December 21, 1888. 6d.

See under XIII., page 199.

*Improvements in Reverting and Utilising By-Products such as are Formed in Processes for Obtaining Chlorine.* R. H. Steedman, Dalmaur, and A. J. Kirkpatrick, Glasgow. Eng. Pat. 18,921, December 28, 1888. 4d.

A SOLUTION of manganese sulphate is treated at a boiling temperature with magnesium carbonate, or magnesia and carbonic acid, manganese carbonate being precipitated and magnesium sulphate remaining in solution.

The manganese carbonate, after filtration and washing, is calcined for the production of oxide suitable for generating chlorine. The solution of magnesium sulphate is evaporated and heated with sodium or potassium chloride, hydrochloric acid being evolved. The residue, consisting of magnesia and sulphate of soda, is treated with water, which extracts sulphate of soda and leaves magnesia ready for use again.

—G. H. B.

*Improvements in the Method of Treating Alkaline Sulphides in Solution or an Aqueous Mixture of the same with Carbonic Acid Gas for the Production of Sulphuretted Hydrogen and in Apparatus therefor.* E. W. Parnell and J. Simpson, Liverpool. Eng. Pat. 19,023, December 31, 1888. 8d.

A SOLUTION or aqueous mixture of alkaline sulphides is charged into a series of receptacles so connected that the contents may be subjected at will to the passage of either of two streams of carbonic acid gas containing an admixture of nitrogen or other inert gas. It is found convenient to have nine receptacles in one system, eight being in operation whilst the ninth is being emptied and refilled. Each stream of carbonic acid is passed through four receptacles at the same time. The first action of the dilute carbonic acid on the alkaline sulphide produces a gas containing very little sulphuretted hydrogen, and this is allowed to escape in any suitable way. As soon as sulphuretted hydrogen is perceptible in the issuing gas, the first receptacle in the series of four forming the preliminary series is disconnected and caused to be the last of the other or final series, whilst a freshly charged receptacle becomes the last in the preliminary series. The other stream of carbonic acid acting on the contents of the final series, each element of which has previously formed part of the preliminary series, produces a gas rich in sulphuretted hydrogen, which is conducted to a gasholder. When the sulphuretted hydrogen in this gas falls below a certain minimum, the first receptacle in the series is disconnected for emptying and recharging. In this way a continuous stream of carbonic acid gas is entering the receptacles at two places and continuous streams of nitrogen and of gases containing much sulphuretted hydrogen are being evolved. Among the advantages of this method of carbonating is the uniform pressure of the gas consequent on the current of carbonic acid gas always passing through the same number of carbonators. The pressure and strength of the sulphuretted hydrogen gas is almost uniform, and the whole plant is kept constantly working except the outstanding carbonator which is being emptied and filled.—G. H. B.

*Improvements in Obtaining Chlorine and in Reverting and Utilising By-Products of the Processes.* R. H. Steedman, Dalmaur, and A. J. Kirkpatrick, Glasgow. Eng. Pat. 881, January 17, 1889. 6d.

COMMON salt, manganese peroxide, and sulphuric acid are mixed together in suitable proportions and furnace for the production of chlorine. The residue, consisting of the

sulphates of soda and manganese, is then dissolved in water and the solution is treated by either of the following processes:—

1. The solution is mixed with magnesium carbonate and heated to boiling, manganese carbonate being precipitated. The solution is evaporated so that the sodium sulphate will crystallise out, leaving the magnesium sulphate in the solution, which is then treated by the process described in Eng. Pat. 18,921 of 1888 (preceding column).

2. The solution is treated with ammonium carbonate, manganese carbonate being precipitated. The solution is evaporated to dryness and heated in contact with steam and carbonic acid; ammonia is evolved and the residue, consisting of sodium bisulphate, is used to decompose sodium chloride in the first operation. Instead of evaporating the solution to dryness, it may be heated with magnesium carbonate for the recovery of the ammonia, the solution of magnesium and sodium sulphates being worked up as before.—(G. H. B.)

*Improvements in the Manufacture of Salt and in Apparatus and Appliances employed therein.* O. E. Pohl, Liverpool. Eng. Pat. 1007, January 19, 1889. 8d.

THE claims in this patent are very numerous and cannot be described without the drawings. The chief feature in the process is the employment of two evaporating pans, one above the other, for the concentration of brine. The two longest sides of the top pan are prolonged downwards so as to dip into the brine of the bottom pan. The products of combustion from the furnace pass through the space thus enclosed, that is, they pass over the surface of the brine in the bottom pan and along the bottom of the top pan, which is suspended in position by rods fixed to overhead cross beams. The ends of both pans are bolted on to the brickwork of the furnace.—G. H. B.

*Improvements in and relating to the Production of Chlorine and to the Manufacture of Sulphate of Soda.* T. Parker and A. E. Robinson, Wolverhampton. Eng. Pat. 2310, February 9, 1889. 4d.

A SUITABLE vessel is divided into two halves by a septum or porous diaphragm. In the one division is placed a solution about half saturated, preferably with sodium chloride, and in the other a similar solution of some sulphate, such as ferrous sulphate. On passing an electric current through the solution, chlorine is evolved at the positive electrode and iron is deposited at the negative, whilst the sulphuric acid which is liberated unites with the soda to form sulphate of soda or salt cake. The chlorine evolved is collected and utilised for manufacturing bleaching powder or for other purposes. (Compare this Journal, 1889, 817, and 1890, 67)

—S. G. R.

*Improvements in Apparatus for the Production of Pyro-ligneous Acid.* J. H. du Vivier, Paris, France. Eng. Pat. 2569, February 13, 1889. 8d.

THIS is a continuous method of treating wood. The retorts are portable and are introduced into and withdrawn from the furnaces by means of specially constructed trucks. The furnaces are set back to back and the waste heat utilised for drying the tarry products. There are six claims made, and two sheets of drawings accompany the specification.—D. A. S.

*Improvements in the Manufacture of Chlorates, and of Magnesium Hydrate suitable for Use therein.* E. K. Muspratt, Liverpool, and G. Eschellmann, Northwich. Eng. Pat. 2786, February 16, 1889. 4d.

THE patentees, in the manufacture of chlorates, prefer to use magnesium hydrate rather than magnesia for the absorption of chlorine. The magnesium hydrate is prepared by treating the oxide or oxychloride, or a mixture of the two, with solutions of the chlorides of magnesium, calcium, strontium

and barium at a temperature of about 80° C. The hydrate formed, when washed and dried, is ready for use. This plan is adopted because the oxide alone does not hydrate itself readily when in contact with water (see this Journal, 1884, 319 and 445).—S. G. R.

*Improvements in obtaining Cyanides from Residuary Liquors formed in Chemical Processes.* J. S. MacArthur, Pollokshields. Eng. Pat. 3072, February 21, 1889. 6d.

THE cyanides may be present in the form of simple, double, or compound cyanides; if zinc be present this should be removed by the addition of ammonium sulphide. To the solution there is added enough acid to make it neutral. If it is alkaline from the presence of soluble carbonates, it can be, if required, made neutral by adding calcium chloride and boiling. To the neutral solution acid is added in sufficient quantity to decompose all the simple, double, and half the compound cyanides present. The solution is then suitably heated, and the evolved hydrocyanic acid absorbed by caustic alkali solutions. To the residual insoluble cyanide in the sludge caustic soda or milk of lime is added and the cyanide thus brought into solution, which after separating the insoluble portion may be either treated as before mentioned or evaporated down and crystallised.

—S. G. R.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

### PATENT.

*Improvements in the Manufacture of Articles of Pressed Glass.* T. Davidson, Gateshead-on-Tyne. Eng. Pat. 2641, February 14, 1889. 4d.

TO the materials generally used for making flint-glass, e.g., sand 560 lb., alkali 210 lb., nitrate of soda 84 lb., are added phosphate of lime 70 lb., "lime spar" 84 lb., and arsenic 35 lb., and the product melted and moulded in the ordinary way for making pressed glass. The articles formed are then exposed locally to a high temperature, when the parts most heated become opaque, those less so translucent, and those kept comparatively cool remain transparent.—B. B.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

### PATENTS.

*An Improved Mode of and Means for Manufacturing Blocks of Artificial Stone.* A. McLean, Brockley. Eng. Pat. 1262, January 23, 1889. 8d.

THE patentee uses a mixture of such materials, e.g., granite chips and Portland cement, as are generally employed for making artificial stone, but adds a larger quantity of water than is customary. The plastic mass is subjected to a pressure of from 1 to 2½ tons per square inch, whereby a block is produced free from air holes and faced with a skin of fine cement, which may be retained or removed, exposing the granite. The press used has its cover provided with pinions working on racks, along which it can be run into place for pressing and removed after the operation. While in position it is held by tension bars actuated by eccentrics and rests, not on the pinions, but on the mould in which is the stone mixture. The head of the ram is fitted with a grooved and perforated plate covered with a sheet of

perforated zinc, above which is a layer of felt, and finally one of cotton or linen cloth; by this means the water expressed from the mixture is provided with an exit, while the cement is retained.—B. B.

*Improvements relating to the Preparation of Silicious Materials used in the Manufacture of Artificial Stone.* A. C. Ponton, Parkstone, B. L. Moseley and C. Chambers, Hastings. Eng. Pat. 2718, February 15, 1889. 6d.

THE patent refers to the manufacture of the substance termed by the patentees "Tridymite" in Eng. Pat. 5808 of 1888 (this Journal, 1889, 462), and 15,256 of 1888, by which they mean the modification of silica obtained by strongly heating flint or sand, whereby the specific gravity is reduced to 2·3, and conversion into amorphous silica is effected. In order to facilitate the handling of the raw material it is, in the case of sand, slightly moistened with a weak solution of an alkaline silicate and moulded into blocks which can be burnt in a kiln until the change indicated above is produced, and then powdered.—B. B.

*Improvements in and Relating to Blocks or Bricks composed of Silicious Materials.* A. C. Ponton, Parkstone, B. L. Moseley and C. Chambers, Hastings. Eng. Pat. 3351, February 25, 1889. 4d.

"SEA-GRIT, shingle, broken flints, or other similar sea or fresh-water-washed aggregates" are graded by sifting, made into a plastic mass by means of a solution of an alkaline silicate, formed into blocks, allowed to dry and fired.—B. B.

*Improvements in the Process of Manufacturing Artificial Stone.* H. H. Leigh, London. From L. H. Clausen, Hamburg, and J. H. Ehlers, Bahrenfeld, Germany. Eng. Pat. 3357, February 25, 1889. 4d.

ONE part of finely powdered and well dried loam, clay, or chalk, is mixed with 1 part of "common resin" heated to about 212°—260° F., the product well stirred, the temperature raised to about 600° F., 4 parts of loam, chalk, or sand, gradually added and the whole stirred at that temperature for a quarter of an hour, after which it is poured on to polished plates or into moulds heated to 106°—150° F. The colour may be varied by suitable additions such as tar. A marbled appearance may be got by painting the interior of the moulds, which will cause a facsimile of the design thus painted to appear on the blocks; the effect of mosaic work may be obtained by inserting fragments of granite or marble previously oiled—with linseed or fish-oil—and parquetry for floors may be similarly produced. If the mixture be heated to about 940° F. for a quarter of an hour, and 5 parts of chalk, loam, or sand stirred in, the product is somewhat darker, durable, and elastic, and can be used for pavements instead of asphalt.—B. B.

## X.—METALLURGY.

*Iron in Spelter made from Blast-Furnace Flue-Dust.* E. Jensch. Zeits. f. angew. Chem. 1890, 13—15.

IN Upper Silesia flue-dust from the blast furnaces of the iron works is largely used by spelter makers. It does not work well alone, partly owing to mechanical loss from its fine state of division, and partly because the sand and oxides of iron and lead it contains destroy the muffles, but it is a useful source of zinc when smelted with other ores, such as blende and silicate of zinc. If worked alone the spelter formed contains too large a proportion of iron—up to 0·71 per cent.—which renders it brittle and unfit for rolling. Spelter made from blende or silicate does not contain more than 0·02 per cent. of iron, the whole of which is derived from the iron tools, moulds, &c. employed, whilst that made from mixtures of blende or silicate, with from 6 to 8 per

cent. of flue-dust, contains no more than 0.04 per cent. of iron. The quantity of iron in the spelter increases as there is more flue-dust mixed with the ores.

The substitution of Cowper and other fire-brick heating stoves for the old east-iron stoves in iron works has led to a more general recovery of the flue-dust, so that its importance as a source of zinc has lately become greater. But although there collects in certain parts of the flues a small quantity of dust very rich in zinc and almost free from iron, yet on the whole the dust recovered from the fire-brick stoves is much poorer in zinc and contains more iron than that formerly recovered when the old east-iron stoves were in use. Not more than 20 per cent. of the flue-dust now recovered contains more than 20 per cent. of zinc, whereas formerly 80 per cent. of the flue-dust contained at least 20 per cent. of zinc. This increased percentage of iron in flue-dust is an important fact to spelter makers.

The author has made experiments to find out how the iron is carried over into the spelter. It seemed probable that it is either carried over mechanically in the form of finely-divided ferrous oxide, or that the presence of chlorides leads to the formation of ferrous chloride which volatilises and in contact with the metallic zinc is decomposed with formation of metallic iron and zinc chloride. By smelting various charges of flue-dust and silicate of zinc alone, and mixtures of these, and a mixture of silicate and ferrie chloride, it was seen that the increase of iron in the spelter was to a very small degree due to the presence of chloride, and that this cause alone far from accounted for the whole of the iron carried over. The author ultimately discovered that the finest portions of flue-dust contained the largest proportion of iron, and he concludes that the iron contained in the spelter is to be ascribed to the carrying over of this fine dust by the vapours and gases evolved in the muffle. An attempt to show whether the iron was dissolved as metallic iron or as ferrous oxide, by heating the spelter in a stream of hydrogen, yielded an unsatisfactory result.

—H. S. P.

*On the Influence of Sulphur in Spelter-making.* E. Orgler.  
Zeits. f. angew. Chem. 1890, 15—17.

The remarks contained in this paper are more or less a criticism of a paper by Voigt in the same Journal, 1889, 71 (this Journal, 1889, 986).

The author maintains that to smelters who use blende the presence of sulphur in roasted blende in the form of sulphide is of great importance, as such sulphur is combined with zinc and retains it in the residues. When lime is present in the ores, as occurs often in the case of silicates, especially of the poorer kind, and these ores are mixed with blende, any lime existing uncombined with sulphur exerts a material influence upon the yield of zinc, especially if the blende, from imperfect roasting, contains an undue proportion of sulphur. The lime in contact with zinc sulphide is converted into calcium sulphide and the zinc is liberated according to the reactions—

Voigt's analyses, showing that in zinc residues one-third of the zinc is combined with sulphur and two-thirds with oxygen, do not agree with numerous analyses relating to Rhenish-Westphalian works, where chiefly blende alone is smelted, which show on the contrary that two-thirds of the zinc in the residues are combined with sulphur, and only one-third with oxygen. The author explains this by the suggestion that, in Upper Silesia, to which Voigt's remarks refer, the ores, which there are found in the Muschelkalk, all contain large quantities of lime and magnesia. If, now, a roasted blende and a poor silicate (which class of ore is specially rich in lime) are smelted together, the lime decomposes any badly roasted blende; but if blende alone be smelted any sulphur present due to incomplete roasting remains in combination with its equivalent of zinc. The more "available" lime (*i.e.*, lime not existing as sulphate or sulphide) there is in the ores smelted the less important is it to a "dead-roast" the blende, an important point when it is remembered that the roasting is the most costly operation as regards both fuel and labour.—H. S. P.

*Outbursts of Gas in Metalliferous Mines.* B. H. Brough.  
Trans. North of England Institute of Mining and Mechanical Engineers, 1889, 59—72.

THIS paper is a collection of the various recorded instances in which gases have been discovered in metalliferous mines. Details of the circumstances attending these discoveries are given, and from a consideration of them the author concludes that the presence of gases in metalliferous mines is not in every case due to the same cause, but may be accounted for by the following hypotheses:—(1.) The decomposition of timber in a mine, and the accumulation of the fire-damp so produced in cavities that are ultimately broken into. (2.) In iron mines, where the iron is not entirely in the state of peroxide, water might be slowly decomposed with the production and accumulation of hydrogen. (3.) The production of fire-damp by the decomposition of the bituminous matter sometimes found in mineral veins or which may be present in beds underneath the ore deposit, the gas finding its way through fissures into the mine workings. (4.) The production of fire-damp by the decomposition of organic matter, in the same way as the hydrocarbons met with in salt mines. (5.) Outbursts of sulphuretted hydrogen, due to the action of acid waters on pyrites ore. (6.) The presence of carbonic acid caused by the action of acid waters, produced by the oxidation of pyrites on limestone or metalliferous carbonates.—A. W.

*Loss on Roasting Gold Ores and the Volatility of Gold.*  
S. B. Christy. Berg- und Hüttem. Zeit. 1889, 224, 290, 318.

THE experiments showed that the volatility in a current of chlorine at 100° is almost nothing. Above this temperature the loss commences to be perceptible, and a maximum is reached at about 250° C., and diminishes to a minimum about the temperature below a red heat, and then again increases, although slowly, to a maximum at something above the fusion point. The increase of volatility is steady between a red and white heat. At incipient red heat the standard loss is nearly 0.05 per cent. in half an hour, at a lower red heat it amounts to the double of this, at a cherry-red to five up to seven times, at a yellow heat to eight times, and becomes at the fusion temperature almost 30 times as great.

From this it is seen how important it is to regulate the temperature in the case of a chlorination roasting process. The action of chlorine on other metals, such as silver, copper, iron, and lead is discussed.

*The Behaviour of Copper at the Temperature of the Reverberatory Furnace.* M. Stahl. Berg- und Hüttem. 1889, 323.

WITH increasing temperature the formation of cuprous oxide diminishes, and in the case of very high reverberatory heats, takes place only to a very limited extent. On the contrary, the absorptive power of copper for gases at the different temperatures of the reverberatory furnace increases. It increases with the temperature and with the purity of the copper. These facts explain why one and the same kind of copper cast at different temperatures exhibits such entirely different properties.

*Quicksilver Deposits on the Pacific Coast.* Eng. and Min. J. 1890, 137.

THE United States Geological Survey has recently published monograph XIII. on the Geology of the Pacific Coast, by Mr. George F. Becker. This is a quarto volume of 486 pages, and is accompanied by an atlas of 11 sheets.

The investigation has been the most detailed of any yet made on the American quicksilver deposits, and for

comparison some of the more important European mines were visited and examined.

The scope of the work has been almost altogether limited to the geological, chemico-geological and lithological points involved.

The Engineering and Mining Journal criticises the report as follows:—

"In the determination of the geological age of the coast range and in his interpretation of the genesis of cinnabar ores, Mr. Becker takes ground at variance with Whitney and other geologists who have preceded him. The controversy about the geology of the portions of California related to the quicksilver districts is still an open one, and Mr. Becker's conclusions will probably be questioned and discussed by students in the same field. In the economic direction Mr. Becker raises a point in his first chapter which will cause some astonishment among mining men. In brief, it is an attempt to deduce the probable amount of quicksilver in the earth's crust, as compared with other valuable metals, from the relative price, cost of production and quantity produced, the conclusion being that quicksilver must be three or four times as abundant as silver, for example. Quicksilver deposits are far less numerous than occurrences of silver (of which latter metal it is very probable that enormous quantities are held in solution in sea water, to say nothing of the known ore deposits and associations with lead and copper ores). And if we compare it with gold, the facts are even more against the theory, for gold occurs in all, or nearly all, quartz, whether in veins, gravel or sand, and in great masses of eruptive, metamorphic and sedimentary rocks, though not in such concentrated form as to be available for mining. So also comparisons with many other metals of similarly wide distribution would be misleading. It so happens that cinnabar, meta-cinnabar, native mercury, &c. when found at all, are usually found in a relatively more bunched condition—that is, more favourably placed for the miner.

"Nor can we agree with Mr. Becker in the broad assertion that the price of a metal is only slightly in excess of its average cost of production. The author assumes a ratio of 100 to 90. Following this comparison out, it would, therefore, appear that the quicksilver which sold at 1.50 dols. must have cost 1.35 dols. per pound to produce; that at 1 dol. would have cost 90 cents; and that at 40 cents 36 cents only. This is manifestly not the case. The quicksilver market is peculiar in being one of limited and widely fluctuating demand, depending mainly on the amount which can be absorbed in amalgamating gold and silver, and in vermilion-making. It is also affected by the policy of foreign monopolies. If quicksilver were a metal of almost universal application, with a practically unlimited market, like iron and steel, there would be more force in the argument."

The following is a summary of Mr. Becker's principal conclusions:—

"Quicksilver appears to be rather more than three times as abundant in nature as silver. The quicksilver produced in the world from 1850 to 1885, inclusive, weighed 1.74 times as much as the silver produced, but the value of the silver was about 16.4 times that of the quicksilver. The great quicksilver-producing localities of the world have been Almaden in Spain, Idria in Austria, Huancavelica in Peru, California, and the province of Kwei-Chau in China. No statistics are known to exist of the Chinese product. The total known products of the other regions take rank in the order in which they are named above, but of late years Peru has produced nothing, and from 1850 to 1885 California yielded about half the total product. The production of Italy is more important than it is usually assumed to be. In 1886 the yield was 7,478 flasks. The production of California, which was nearly 80,000 flasks in 1877, was only about 30,000 in 1886. [It was 25,650 flasks in 1889.—*Ed. E. and M. J.*]

"A chain of quicksilver deposits of very greatly varying commercial importance almost girdles the world. Beginning in Spain, these deposits are distributed along the great chain, including the Alps, Caucasus, and Himalayas, to China; thence through Japan along the eastern edge of the Asiatic continent to the Arctic circle. Beginning again in Alaska,

the deposits follow the western Cordilleras down to Chili. Brief descriptions of the more important or more interesting of these deposits are given in Chapter II., and serve as an introduction to the discussion of the deposits of the Pacific slope.

"The sedimentary rocks of the coast ranges of California are almost all composed of granite detritus. A portion of these have been subjected to very intense metamorphism, and have been converted into thoroughly crystalline rocks, in part schistose. These rocks are of Cretaceous age, and are grouped as pseudodiorite, pseudodiorite, glaucophane-schists, plthanites, and serpentine. Very elaborate field studies, microscopical examinations, and chemical analyses of these rocks are given in Chapter III., which is mainly devoted to the investigation of their origin and the processes by which they have become recrystalline. The conclusion reached is that dynamical action, together with warm waters carrying magnesian salts and silica in solution, effected the metamorphosis at the epoch of an exceedingly violent upheaval. This chapter also includes an investigation of concretions in sandstone, which are referred to the action of organic matter, and the analysis of the conditions under which decomposition will produce rounded nodules like pebbles.

"The massive rocks of the quicksilver areas include granite, ancient porphyrites, andesites, rhyolite, and basalt. A new group of andesites is discussed, for which the name *asperites* is suggested. It is shown that these rocks are of variable mineralogical composition, even in the same eruptions, while all of them share a trachytic habitus. The name is simply a latinised equivalent of trachyte. Very remarkable andesitic and basaltic glasses occur near Clear Lake in areas of unusual size. These glasses are extremely acid, but contain also a very high percentage of alkalis, and it is because of this peculiar chemical composition that they have failed to crystallise, not because they have cooled more rapidly or under less pressure than the accompanying crystalline rocks. An attempt is also made to show that the original crust of the earth was granite, and reasons are given for believing that the primeval rock is exposed in California. The lavas burst through the granite, and the conclusion is reached that they cannot possibly consist of remelted sediments.

"The historical and structural geology of the quicksilver belt is discussed in Chapter V. It is shown that the metamorphosed rocks pass over into early Cretaceous beds containing a very characteristic fossil of the genus *Ancella*. Soon after the era in which this mollusk lived—the Neocomian—occurred the great upheaval which induced the metamorphism. The next strata in point of age comprise a hitherto undetected group of the middle Cretaceous called the Walla beds. They were laid down unconformably on the already metamorphosed Neocomian. At the very end of the Cretaceous the Chico series were deposited for the most part on the metamorphic rocks and unconformably with them. Following the Chico are the Tejon beds, which are here regarded as Eocene; but there was continuity of life and of sedimentation from the Chico to the Tejon, or from the Cretaceous to the Tertiary—a state of things detected nowhere else in the Northern Hemisphere. Upon the Tejon lie the Miocene rocks with no notable nonconformity. The close of the Miocene was marked by an important upheaval, which was recognised by early observers. The volcanic period seems to have begun nearly at this time. The end of the Pliocene was also marked by disturbances, and most of the *asperites* seem to have been erupted at this epoch. The ore deposits stand in close relation to the volcanic phenomena and are probably nearly or quite all Post-Pliocene.

"The gold belt of California contains *Ancella*-bearing beds in Mariposa and Tuolumne counties. This shell is of the same species as that in the coast ranges, and the first known upheaval of these mountains was contemporaneous with an important addition to the Sierra Nevada. A description of various forms of *Ancella* from different portions of the world, by Dr. C. A. White, with plates, forms an appendix to this chapter.

"Descriptive chapters follow dealing with the various districts, of which detailed surveys were made. Each of these districts affords special facilities for the study of some

special topic. The Clear Lake region contains freshwater Pliocene beds, and in it the age of audesities can be determined. It also contains remarkable areas of volcanic glass. At Sulphur Bank cinnabar is being precipitated from heated waters largely by the action of ammonia. At Knoxville, besides the ore deposits, there are admirable opportunities for determining the age of the metamorphic rocks and for studying the process of alteration. At New Idria the nonconformity between the metamorphic rocks and the Chico and the continuity between the Chico and Tejon appear. The New Almaden mine is particularly well adapted for the study of the structure of the ore deposits. At Steamboat Springs cinnabar is being deposited without the complications introduced by the presence of ammonia.

"In Chapter XII. the Great Western, Great Eastern and Napa consolidated mines are described, and in the next chapter more or less information is giving concerning each of over fifty minor deposits on the Pacific slope. Some of these have been productive mines, while others are mere prospects of only a geological interest.

"A general description of the deposits described follows, including the enumeration of the gangue minerals, the microscopical character of ores, &c. It appears that the cinnabar has been deposited solely in pre-existing openings, and never by substitution for rock. The fissure systems, which are always present, are very irregular, and deposits cannot be conveniently classified according to existing systems. A new descriptive term, 'chambered vein,' is suggested, which would include nearly all the deposits. A chambered vein is defined as a deposit consisting of an ore-bearing fissure and of ore bodies contiguous with the fissure which extend into the country rock. It appears that all of the deposits described have probably been deposited in the same way from hot sulphur springs.

"Chapter XV. deals with the processes by which the ore has been dissolved and precipitated in nature. It is shown by experiment and analysis that cinnabar unites with sodium sulphide in various proportions, forming soluble double sulphides, and that these compounds can exist in such waters as flow from Sulphur Bank and Steamboat Springs either at ordinary temperatures or above the boiling point. Metallic gold, iron pyrites, copper pyrites, and other minerals found with cinnabar are also soluble in the same solutions.

"A discussion of the origin of the ore concludes the investigation. It is shown that the quicksilver is probably derived from granitic rocks by the action of heated sulphur waters which rise through the granite from the foci of volcanic activity below that rock.

"For the convenience of those who consult the report the separate chapters are made as far as possible independent of one another, a plan involving a certain amount of repetition. Further, to facilitate the use of the volume, the last chapter presents a summary of those which precede it."

#### PATENTS.

*Improvements in the Manufacture of Iron and Steel alloyed with Nickel.* H. Schneider, Le Creusot, France. Eng. Pat. 16,567, November 14, 1888. 4d.

NICKEL scrap in any form is melted in any suitable furnace with cast iron or steel, with the production of alloys of steel and nickel containing from 5 to 30 per cent. of the latter. These alloys are said to be suitable for the manufacture of armour plates, projectiles, &c.—A. W.

*Improvements in the Manufacture of Iron and Steel alloyed with Copper.* H. Schneider, Le Creusot, France. Eng. Pat. 16,568, November 14, 1888. 6d.

THE patentee claims the manufacture in a blast-, cupola-, or reverberatory furnace, of cast iron or steel, containing variable percentages of copper, such alloys being applicable to the production of armour plates, &c. Copper ore, scrap, or a mixture of matte and scrap, may be introduced into the ordinary blast furnace or cupola, or the copper may be first made into a cuprous coke. The product generally contains from 5 to 20 per cent. of copper, but the patent is not confined to these proportions.—A. W.

*Improvements in the Wet Method of extracting Gold from Crushed Ores or other finely divided Auriferous Material.* J. H. Pollok, Glasgow. Eng. Pat. 16,796, November 19, 1888. 4d.

THE patent relates to the extraction of gold from crushed quartz or other auriferous material and especially from refractory ores, float gold ores or tailings, more particularly in connexion with the process of extracting gold from crushed ores by means of chlorination under hydraulic pressure as described in Eng. Pat. 17,195 of 1887 (this Journal, 1888, 678). The improvements consist in removing the air from the vessel in which the ore is placed for chlorination, and in forcing in water heated to about 60° C.

The ore, suitably crushed, and if desirable concentrated and roasted, with or without salt or other reagent according to its nature, is charged together with the requisite reagents into a suitable revolving cylinder properly protected from the corrosive action of the chlorine evolved in the operation. The reagents used to generate chlorine are charged into the cylinder, the one before and the other after the ore, to avoid the liberation of chlorine before the closing of the cylinder and the revolving of the same. After the ore and reagents have been charged, the air is removed from the cylinder by a suitable stop-cock placed for that purpose, and this is effected either by any air-removing device such as an air-pump or by driving out the air by the admission of water. After the air is removed, or simultaneously with its removal, water is forced into the cylinder, and this water is heated to 60° C. either during its introduction (by means of a steam injector) or previously to or during the revolution of the cylinder. "As soon as the cylinder is completely filled with ore, reagents, and water, the steam acts as a very convenient and economical water-forcing device for it presses on the condensed water in the supply pipe, and forces it into the cylinder, thus exerting hydraulic pressure in the cylinder equal to the steam pressure in the boiler." The cylinder is next revolved, and in the absence of air and at or about the temperature of 60° C., and under the hydraulic pressure, the chlorinating liquid rapidly attacks and dissolves the gold. When the action is complete the chlorine is blown or aspirated off and the ore and solution discharged into a suitable filter. In cases where copper and silver are present with the gold the liquid may be made, by means of a steam ejector, to circulate through the ore in a hot state for some time before removal from the filter, as this greatly assists the solution of the silver.

This method is equally applicable when bromine or iodine is used in the place of chlorine.—H. S. P.

*An Improved Process of Extracting Iron from its Ore and of Refining or Purifying Iron.* A. Q. and A. Brin, London. Eng. Pat. 17,858, December 6, 1888. 4d.

IRON ore, charcoal, lime, and sodium chloride are heated together in any convenient furnace. The nascent chlorine from the salt is stated to remove the impurities from the iron, especially the phosphorus and the sulphur. The process can also be applied to the purification of wrought iron and the refining of steel.—A. W.

*A New or Improved Apparatus for Treatment of Auriferous Sand and other Matters containing Free Gold.* A. Clement-Conti, Foleto, Italy. Eng. Pat. 18,004, December 10, 1888. 8d.

THIS is an apparatus, which is said to be inexpensive and portable, for washing auriferous sand or other alluvial deposits, or mixtures containing particles of free gold. The sand is first introduced upon a wooden or metallic shoot, and is then washed over a grating, so as to separate pebbles and coarse sand. The fine sand and gold which pass through the grating are then carried by the flow of water into a funnel provided with two overflows, so as to keep the level of the water in it constant, and to obviate vibration and regulate the force of water passing through the funnel. This funnel is adapted to a tube passing nearly to the bottom of a cylindrical vessel, and it can be raised or lowered so as to regulate the water-pressure in the cylinder.

The floor of the cylinder is in the shape of an inverted cone, and a plug is fitted into a hole at the apex. The particles of gold settle on this floor, whilst the lighter sand passes out of the cylinder by a number of syphons, which empty into an annular trough surrounding the cylinder, in which some mercury is placed, to catch any fine particles of gold that pass over with the sand. On the top of the cylinder is placed a trough or cistern, kept filled with water, which is allowed to flow into the cylinder by pipes passing through the bottom of the trough, and reaching nearly to the bottom of the cylinder. More water being allowed to flow into the cylinder than can be carried away by the syphons, overflow pipes are fitted at a level near the top of the cylinder, which discharge into the same annular trough as the syphons. The gold which collects on the floor of the cylinder is, when necessary, allowed to pass into a receiver placed below by removing the plug in the cylinder-bottom. The operation may be carried on by a successive number of concentrations.

Drawings of the apparatus accompany the specification. The size of cylinder represented is only 36 centimetres in diameter, but this size is calculated to treat 10,800 litres of sand passing through the sieves in 10 hours. These 10,800 litres of sand are reduced to 10 litres of rich sand, and this is then treated in a much smaller apparatus, where it is reduced to  $\frac{1}{2}$  or  $\frac{2}{3}$  litre, and then again in a still smaller apparatus to 50 cc., consisting of gold and iron, and a few grains of sand. It is then dried, and the iron removed by a magnet.

Another way of using the apparatus is to introduce mercury into the washing cylinder.—H. S. P.

*Improvements relating to the Extraction of Gold, Silver, and Lead from Substances containing the same, and to Apparatus therefor.* A. B. Cunningham, Islington. Eng. Pat. 28, January 1, 1889. 8d.

THE ore is heated with caustic soda or potash to fusion of the caustic alkali. If an insufficient quantity of lead be present, a requisite quantity of galena or other substance containing lead is added.

The operation may be carried out on the hearth of an open reverberatory furnace provided with an iron bottom and sides, or lined with a fused caustic bottom, or with any other lining calculated to resist the action of caustic alkali. But in preference it should be carried out in a cast-iron (or wrought-iron) vessel or pot. When sulphides are treated, this pot is lined with rings of cast iron, placed one on top of the other, and adapted to the internal form of the pot. This lining is easy of adjustment, and can be replaced when required. A drawing of a suitable pot and furnace for heating the pot accompanies the specification.

In treating galena, the patentee finds 30 per cent. by weight of caustic alkali gives a good result. The lead collects at the bottom of the vessel, and carries down with it the gold and silver, which is then recovered by cupellation or other suitable process.—H. S. P.

*Improvements relating to the Extraction of Aluminium from Cryolite and other Substances.* C. Netto, Dresden, Germany. Eng. Pat. 359, January 8, 1889. 6d.

THE basis of this patent is founded on the fact that during the extraction of aluminium by sodium the impurities generally associated with the alumina are reduced in the early stages of the operation. The process, therefore, is divided into two parts. The mixture of cryolite and salt is first treated with one-third of the theoretical amount of sodium and is then run off from the metal containing the impurities thus produced, and subjected to the action of the remainder of the sodium, in which latter operation pure aluminium, containing only 0.5 to 1.0 per cent. of impurities, is obtained. This fractional reduction, which is not necessarily confined to two parts, or to the division of the sodium as above, is claimed for application to all processes for obtaining aluminium. The crucibles or other vessels in which the operations are performed are preferably lined with basic material as a safeguard against silicon and other impurities.—A. W.

*Improved Means of Extracting Precious Metals from Ores.* J. B. Hannay, Loch Long. Eng. Pat. 841, January 16, 1889. 8d.

RELATES especially to the extraction of gold from its ores in the form of chloride. The patent is for an apparatus devised for this purpose, which consists of a chlorinating vessel, a set of circulating pumps, a filter-press, and a chlorine pump, or sets of these with suitable communicating pipes, cocks, and valves. The ore is first reduced to a fine powder and then mixed with water or chlorinated water, so as to form a sludge capable of being pumped. The chlorinating vessel is charged with this sludge, and the pumps cause the latter to circulate by drawing it from the upper part and discharging it into the lower part of the vessel. Meanwhile, chlorine gas is pumped into the vessel, preferably at a pressure considerably above that of the atmosphere. After circulation has gone on until the most part of the gold is dissolved, the sludge is delivered by the circulating pumps to the filter-press, additional pressure being obtained if needed by using the chlorine pumps to force air into the upper part of the vessel. The liquid issuing from the filter-press may be treated in any of the known ways for separating the gold from it, or it may be used over again with a fresh quantity of ground ore until it is of a desirable strength. It is advantageous to charge the chlorinating vessel with an excess of chlorine above that required for combination with the gold contained in the sludge; and to recover this excess, before discharging the contents of the chlorinating vessel into the filter, a little steam is blown into the vessel and the expelled chlorine collected in a gasholder or led to another chlorinating vessel; or an aspirator may be used for drawing off the excess of chlorine. When silver is present the blocks which are taken from the filter-press are reduced again to a sludge and subjected to a similar treatment with a suitable solvent instead of chlorine. Other means of filtering may be used instead of a filter-press.—H. S. P.

*An Improved Method and Means for separating Metals and Heavy Minerals from Ores.* R. Stanfield and T. Clarkson, Battersea. Eng. Pat. 890, January 17, 1889. 8d.

THE ore, after being brought to a fine state of division, is fed, with or without water (preferably without water) into a suitable receptacle revolving about a vertical or suitably-inclined axis, and provided at its circumference with holes through which the particles of ore are ejected. These holes may be straight or curved and arranged radially or otherwise, and may be in one place so as to project the material horizontally, or on the surface of a cone so as to project it upwards or downwards as desired. The vessel may be also arranged with straight or curved projecting tabular arms. If the particles of ore are of the same size they will be separated according to their densities—the denser particles being projected farthest; if, however, the particles differ in size, it is advisable to perform a preliminary sizing operation. A receiver is placed around this centrifugal separator at a lower level. This receiver may be divided into any convenient number of concentric compartments, so as to divide the material deposited upon it into any required number of parts, and brushes or scrapers may be provided to remove the contents of each division of the receiver. The receiver may also be kept moist by water or steam or any other suitable fluid. A current of air may be made to operate upon the particles of ore as they fly from the rotating vessels so as to assist their deposition upon the receiver.

The separation may be assisted by adding a heavy substance (such as mercury) which would combine with the metallic portion of the material.

The machine is applicable to ores of gold, silver, tin, lead, copper, or any other metal. It may be either used for sizing purposes or for separating metals and minerals from ores, and the improved receiver may be used with any form of centrifugal separator or sizing apparatus.—H. S. P.

*Improvements in the Manufacture of Iron and Steel.* J. Richardson, Pocklington. Eng. Pat. 1099, January 21, 1889. 4d.

THREE solutions are prepared: the first is prepared by dissolving in water with the aid of heat certain proportions of nitrate of soda, nitrate, prussiate, and bichromate of potash, and mixing with the solution "naphtha, paraffin, or certain other hydrocarbons;" the second solution is made by dissolving gum catechu and raw sugar in water; and the third is a solution in water of pearlash, acetic acid and chloride of lime. These three solutions are mixed together and fed into a boiler, and there heated. The vapour obtained is then passed through, over or under the molten iron, until the quality of the metal is sufficiently improved.—A. W.

*Improvements in or appertaining to the Process of Galvanising Iron and Steel.* T. B. Saunders, Cleckheaton. Eng. Pat. 1571, January 29, 1889. 6d.

THE improvements relate to the removal and recovery of the ammoniacal fumes formed in the galvanising tank when sal-ammoniac is being used. The tank is covered with a convenient hood, connected by means of a pipe with a condensing tower. The fumes are drawn through into the latter, where they are condensed by means of water or acid spray.—A. W.

*Improvements in the Manufacture of Aluminium and Alloys thereof.* L. Petit-Devancelle, Paris, France. Eng. Pat. 7013, April 26, 1889. 8d.

THE metal with which the aluminium is to be alloyed is melted in a suitable furnace, preferably in a rotatory furnace such as a Dank's furnace, the aluminium being then added in the form of a salt of aluminium. To assist the thorough mixing of the contents of the furnace, a helical rib or flange is fixed upon the inside wall of the furnace. This rib may be made of iron or fire-brick.

For producing alloys of iron and aluminium, any of the ordinary compounds or substances containing aluminium may be used with the iron; for alloys of aluminium with other metals, for example, copper, a silicate of aluminium only should be used.

If it is desired to obtain the aluminium in an unalloyed condition, the aluminium is recovered from the alloy by ligation, distillation, or oxidation of the metal used to form the alloy, the aluminium remaining as a residuum.

—H. S. P.

*An Improved Process for the Treatment of Auriferous and Argentiferous Antimony Ores.* C. Schreiber and H. Knutsen, Broken Hill, New South Wales. Eng. Pat. 14,235, September 10, 1889. 6d.

IN the usual method of roasting these ores before amalgamation there is a considerable loss of both gold and antimony. The gold occurs in metallic state, and generally on the surface of the antimony at the points of contact with the quartz. During the roasting the particles of gold become coated with a film of oxide of antimony which prevents the subsequent action of the mercury. Moreover, a certain quantity of antimony becomes amalgamated, and causes the mercury to "sicken." If the ore be roasted with salt a basic chloride of antimony is formed which forms a protective coating on the particles of gold, so that a similar difficulty in amalgamating is experienced.

The improved process consists in "leaching" or lixiviating the sulphides and oxides of antimony with a solution of a sulphide of the alkalis or alkaline earths, preferably with a solution of sodium sulphide.

The ore is first hand-picked into three classes, more or less, viz., No. 1 ore containing upwards of 25 per cent. of antimony; No. 2, containing from 5 to 25 per cent.; and No. 3, containing less than 5 per cent. It is then crushed and passed through a sieve of not less than 900 meshes to the square inch. It is then taken to the lixiviating pans or agitators, where it is treated with a solution containing

sulphide of sodium in a rather larger proportion than is required by the equation  $\text{Sb}_2\text{S}_3 + 3 \text{Na}_2\text{S} = 2 \text{SbNa}_3\text{S}_3$ ; e.g., in the proportion of 12 parts of  $\text{Na}_2\text{S}$  to 17 parts of  $\text{Sb}_2\text{S}_3$ . If sulphide of barium or calcium be used an amount is taken proportionate to the molecular weight of the salt used.

In practice, to obtain a concentrated solution of the antimony double salt, it is best to wash the ore first with a solution that has been twice used, then with one that has been once used, and finally with fresh liquor.

The ore being now free from antimony can be easily amalgamated for the recovery of the gold and silver.

The antimony is recovered from the solution of the double salt by means of electrolysis. For this purpose care must be taken to regulate the strength of the current to the degree of concentration of the solution. The reaction at the cathode may be represented by the equation—

and at the anode by—

During the process a quantity of caustic soda is from time to time added to convert the sodium bisulphide into sodium sulphide:— $\text{Na}_2\text{S}_2 + 2 \text{NaOH} + 2 \text{H} = 2 \text{Na}_2\text{S} + \text{H}_2\text{O}$ .

To increase the conductivity of the solution a small quantity of common salt is added to it. The liquors are circulated continuously from cell to cell, until the whole or nearly the whole of the antimony is precipitated. The residual solution of sodium sulphide is then returned to the lixiviating pans. "In practice it is considered that all solutions containing a certain quantity of the double salt of antimony will repay treatment by electrolysis," strong solutions being diluted with weak ones, and weaker ones increased in strength by dissolving in them sulphide of antimony from another part of the process. In the third class the liquor obtained by treating 5 per cent. and lower grade ores is worked otherwise. From this it is proposed to separate the antimony by allowing the solution to drip continuously down a tower about 20 ft. high, so as to come in contact with carbonic acid, or preferably with sulphurous acid, which is allowed to enter at the bottom of the tower.

The reactions are represented as follows:—

When carbonic acid is used, and especially in the case when sulphide of calcium or barium is employed, the precipitate at the bottom of the tower contains insoluble carbonates. The whole precipitate is then reduced in a muffle or reverberatory furnace and smelted for antimony. But when sulphurous acid is used there are formed soluble hyposulphite and bisulphite of sodium, from which the precipitated sulphide of antimony is removed by filtration and the whole of the sodium sulphide originally used can be recovered from the filtrate by evaporation and reduction with powdered coke or charcoal. The sulphide of antimony is placed in canvas bags and suspended in the electrolytic cells for strengthening a weak solution or for replacing the dissociated trisulphide. The metallic antimony is collected, washed with hot water, pressed into cakes, and smelted in crucibles for the market.—H. S. P.

*Improvements in the Manufacture of Iron and Steel.* G. Archbold, New York, U.S.A. Eng. Pat. 15,824, October 8, 1889. 4d.

WITHERITE or other salt of barium is introduced with the ordinary charge into the blast furnace with the object of removing the phosphorus and sulphur and producing pig iron free therefrom. These impurities can also be removed from iron by treating the latter with the barium salt in the Bessemer or other converter, the quantity used being the theoretical amount necessary to produce sulphide and phosphide of barium. The theory is as follows: The barium is converted at the temperature of the furnace

into cyanide which reacts on the iron phosphide, producing barium phosphide and ferrocyanide of iron, which latter is converted into "refractory carbide of iron which mixes with the slag." When much silicon is present it is found advantageous to use also barium nitrate in addition to the carbonate.—A. W.

*Improvements in the Manufacture of Iron and Steel.* R. F. Ludlow, Springfield, U.S.A. Eng. Pat. 16,474, October 18, 1889. 8d.

This patent applies to the oxidation of the impurities in iron by air, the claim being that instead of the air being directed on to or through the metal from any one position, it is blown upon the surface at an angle and at constantly varying places, which gives the mass a "practically uniform disturbance."—A. W.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### PATENTS.

*Improvements in the Method of and Means for separating Matters in Solution by Osmose, Dialysis, or Diffusion, or by Electrolysis, or by a Combination of those Processes.* J. Marx, Ulm, Germany. Eng. Pat. 2367, February 16, 1888. Amended October 22, 1889. 8d.

THESE improvements have been already described in this Journal, 1889, 288. The emendations appear to consist in the correction of printer's errors in the text of the original specification—no alteration being made in the claims.—O. H.

*Improvements in the Production of Oxygen and Hydrogen in Large Quantities by Means of the Electrolysis of Water, applicable for Ballooning and other Uses.* D. Latchinoff, St. Petersburg, Russia. Eng. Pat. 15,935, November 3, 1888. 11d.

To obtain oxygen and hydrogen in large quantities a large current, say 600 ampères at a potential difference of 110 volts, is led through three parallel set of electrolytic baths, each set containing 44 separate cells connected in series for this particular number of volts. Each cell contains either water acidulated with sulphuric acid or a 10 per cent. solution of caustic soda, and immersed in the solution are two carbon cathodes and a lead anode, or iron plates may be used. Suitable gas collectors are arranged over each cell enabling the two gases to be dried and carried off to suitable gas-holders. By this means, the patentee states, 640 cubic metres of hydrogen can be obtained in 60 hours, and the value of the oxygen at the current price more than pays all expenses.—B. T.

*Improvements in Electro-Chemical Generators.* F. J. Brougham, London. From La Société Perreux Lloyd and Fils, Paris, France. Eng. Pat. 18,858, December 24, 1888. 8d.

A NOVEL form of battery is described in which the heat generated by the internal electrical resistance is utilised to heat and concentrate the solutions employed to such a degree that the salts formed will crystallise out upon cooling. The battery is so constructed that the solutions can be heated by steam if the heat obtained electrically be not sufficient. The salts obtained are of more value than the original materials employed, so that the electricity is obtained as a by-product. The depolariser, nitric acid, is used over and over again, the nitric oxide formed being converted by the oxygen of the air into hyponitric acid, and then reconverted into nitric acid in suitable condensing towers.—B. T.

*Improvements in and Appertaining to the Manufacture of Metals or Metallic Alloys by Means of Electricity.* G. C. Dymond, Liverpool. From J. M. A. G. Lécuyer, Courbevoie, France. Eng. Pat. December 29, 1888. 8d.

THE raw material is incorporated with carbon and made into electrodes; an electric arc is then formed between a pair of these electrodes over the bed of a reverberatory furnace. The ore in the electrodes is reduced and the metal falls into the hot bed of the furnace. In some cases alloys are formed by mixing other metals, as powders, with the materials of which the electrodes are composed. Details of construction of apparatus are described, one of which consists of jointing on fresh electrodes to the unburnt ends of the partially used ones, so as to enable the process to go on continuously.—E. T.

*Improvements in Secondary or Storage Batteries.* T. Cuttriss, Leeds. Eng. Pat. 997, January 19, 1889. 6d.

A PLUG or core is put into the containing vessel, of such a size and shape as to leave a narrow space all round between it and the walls of the vessel. This space is then filled with a paste of oxide of lead and sulphuric acid, which when hardened forms the active material of one electrode of the cell. When the containing vessel is non-metallic it is lined with platinum or lead, or strips of these materials are bedded into the paste so as to make good electrical contact with it.—E. T.

*Improvements in Secondary Battery Plates, Elements, or Supports.* J. S. Sellon, London. Eng. Pat. 1460, January 26, 1889. 6d.

To prevent the active material falling out of the plates a compound plate is used, so constructed that the ribs on one side are not coincident with those on the other, but are situated reversely so that the active material interlaces between these ribs, and is at the same time made up of one continuous mass instead of being made up of separate individual pellets as usually constructed.—B. T.

*Improvements in the Construction of Secondary Batteries.* G. Philippart, Paris, France. Eng. Pat. 1673, January 30, 1889. 8d.

THE supports are made of lead, compressed, or cast under pressure. The active materials are made into a thin paste with glycerin or some such substance and spread over a piece of fabric, such as felt, asbestos cloth, &c. This layer of paste is pressed into the fabric, the prepared fabric being then heavily pressed into contact with the lead supporting plate. The layer of active material may be further protected by an external sheet of perforated celluloid or such material, and the electrodes may be of any desired shape.—E. T.

*Improvements in and Relating to the Production of Chlorine and the Manufacture of Sulphate of Soda.* T. Parker and A. E. Robinson, Wolverhampton. Eng. Pat. 2310, February 9, 1889. 4d.

See under VII., page 189.

*Improvements in Electrical Accumulators or Secondary Batteries.* W. E. Langdon, Derby. Eng. Pat. 5816, April 5, 1889. 8d.

THE object is to get rid of the spray given off during charging. Each cell has a cover whose edge fits into a groove running all round the top of the cell, and filled with liquid. The cover has a small aperture in the crown, through which any spray-laden gas passes into a "decomposing cell." This cell may be said to consist of three concentric tubes. The first, or innermost, is covered as by a cap, by the second, which is closed at the top. The gas given off passes up the first tube, down between the first and the second, and then up between the second and third. The space between the two latter is packed with lime or some such material capable of absorbing the spray.—E. T.

*Improved Supports of Secondary Batteries.* G. E. Heyl, Charlottenburg, Germany. Eng. Pat. 13,800, September 2, 1889. 6d.

THE object of the improvement is to get an elastic support that can expand and contract with the active material. Using a perforated plate, the ribs forming the boundary of each mesh, are themselves perforated by narrow slits so as to split what was a common boundary to two adjacent meshes into two distinct boundaries, one for each mesh. The thin boundary walls may afterwards be turned inwards so as to make the opening to each mesh smaller than the interior. Neither the perforations nor the slits need extend right through the plate, and there may, if preferred, be perforations and slits on each side separated from each other by a thin continuous septum of lead.

—E. T.

*Improvements in Thermostats.* H. Cortland, Toronto, Canada. Eng. Pat. 15,800, October 8, 1889. 6d.

A METALLIC tongue free at one end but fixed at the other is stretched diametrically across an annular metal case, but electrically insulated from the case, the tongue carrying at its centre an adjustable screw, one end of which presses against the centre, on the concave side, of a concavo-convex hard rubber diaphragm carried by the same metal case. As the diaphragm expands or contracts with changes of temperature, the position of the free end of the tongue alters and makes or breaks an electrical contact, which can be used to give a signal in any well-known way.—B. T.

*Improvements in Devices for Connecting the Plates of one Electrical Battery with another Battery or Batteries, and with a Switch-board or Transmitting Device.* W. F. Smith, Philadelphia, U.S.A. Eng. Pat. 15,819, October 8, 1889. 8d.

THE coupling device is such as might be made in the following manner. A short length of tube, screwed over a part or the whole of its outside, is split longitudinally into two, and one-half attached perpendicularly, near its middle, to the end of the strip from one cell, while the other half is similarly connected to the strip from an adjacent cell. To couple the two cells the two halves of the tube—each attached to its strip—are brought together and a "thimble" screwed over them, so as to connect them rigidly together. Instead of the outside of the tube and the inside of the thimble being screwed, they may be slightly coned to fit each other. A little mercury is put at the bottom of the thimble to ensure good connexion, and any parts may be electro-plated to resist amalgamation. Branch or other connexions can be made by a plug fitting into the jointed tube and provided with a flexible conductor.—E. T.

*Improvements in Frames for Supporting the Plates or Elements of a Secondary or Storage Battery.* W. F. Smith, Philadelphia, U.S.A. Eng. Pat. 15,820, October 8, 1889. 8d.

A FRAME of lead or suitable material is used to support a series of plates to be formed, the said frame being provided with a lug for connecting up in the usual manner, and also with an auxiliary loop or extension, two forms of which are shown, to be used during the process of formation of the plates, both as a connexion and also as a means of lifting the plates, thus avoiding all damage to the lug which is to be used when the plates are in their finished state.—B. T.

*Improvements in the Method of Electrolytically Reducing Plates of Metallic Salts to a Metal State to "Form" the Electrodes of Secondary or Storage Batteries.* S. C. C. Currie, Philadelphia, U.S.A. Eng. Pat. 15,821, October 8, 1889. 8d.

IN the ordinary methods of reducing a salt of lead to the metallic state, the salt is held in a stout frame of suitable metal and treated electrolytically; as, however, the salt is usually a poor conductor, the formation is but slow, and

does not take place uniformly throughout the plate. To obviate this, and to accelerate the formation, a perforated plate of conducting metal is pressed down upon the surface of the salt, and the whole is treated electrolytically in the usual manner, the plate to be formed being connected to the negative pole of the source of electricity.—B. T.

*Improvements in Galvanic Batteries.* W. E. Irish, Brooklyn Village, Ohio, U.S.A. Eng. Pat. 16,036, October 11, 1889. 8d.

ZINC treated with an amalgam of mercury and tallow is used for the positive electrode, and is immersed in a solution of sulphuric acid, Mecca, or other suitable oil, and sodium sulphate in suitable proportions, while the negative electrodes are composed of carbon in the form of plates or pencils. Similar plates or pencils of carbon are also placed outside the porous pots, close to but not in contact with the zincs, to reduce the resistance of the element, or auxiliary plates of iron are used adjacent to and connected with the zinc in order to prevent waste of the latter while the battery is not working.

The negative electrode is immersed in a solution containing the following in suitable proportions:—Bichromate of potash, chlorate of potash, nitrate of soda, flour of sulphur, chromic acid, nitric and sulphuric acids. The battery solutions may be covered with a suitable oil or paraffin wax to prevent escape of fumes.—B. T.

*Improvements in Moulds for Casting the Plates of Secondary or Storage Batteries.* W. Shapleigh, Camden, New Jersey, U.S.A. Eng. Pat. 16,662, October 22, 1889. 8d.

THE improvements are for casting small blocks or plates of active material, round which a frame of better conducting material may afterwards be cast. The mould is made in two symmetrical parts hinged together. The liquid material is poured down a central feeder to the bottom of the mould, and thence passes into vertical risers. "Knife edge" slits extend from the sides of these risers to the matrices in which the blocks are to be cast, and branch air-ways extend from the top of each matrix, to which they are connected by other knife-edge slits, to vertical main air-ways communicating with the exterior. It is claimed for this mould that very solid homogeneous blocks can be cast without air-bubbles forming, and that such blocks can be readily separated from the mould and from each other.—E. T.

*Improvements in Treating and Rectifying or Ageing Alcohol or Alcoholic Liquors or the like by Electricity.* A. de Meritens, Paris, France. Eng. Pat. 16,947, October 26, 1889. 4d.

See under XVII., page 205.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

*Mineral Lubricating Oils.* A. Kunkler. Dingl. Polyt. J. 274, 276—284.

THE author, in giving his experience of testing oils, does not consider an oil-testing machine necessary.

He gives in tabular form the results obtained on testing a large number of Russian, American, and German mineral oils, and also of rape, olive, castor, linseed, and other oils.

The points determined were:—1. Specific gravity at 17.5° C., in most cases by the pycnometer, in a few by the Westphal balance. 2. The temperature at which vapour is first given off. 3. The flashing point. 4. The burning point. Both the latter were determined in a small porcelain

crucible. 5. The freezing point was taken in an ordinary sized test-tube. 6. The colour. 7. The viscosity at 20°, 30°, 50°, 60°, 70°, 100°, and 150°, the viscosimeter used being that of C. Engler. The following are some of the results obtained:—

Class of Oil.	Sp. Gr. at 17.5°.	Flashing Point.	Viscosity.	
			50°	100°
Russian cylinder oils.	911—923	183°—238°	10.2—16.2	2—2.8
Russian machine oils.	893—920	138°—197°	5.8—6.3	1.5—1.8
Russian spindle oils.	893—895	163°—167°	3.1—3.1	1.4—1.5
American cylinder oils	886—899	280°—283°	..	4.1—4.8
American machine oils	884—920	187°—206°	4.2	1.6
American spindle oils	908—911	187°—200°	3.1—3.3	1.4—1.6
Rape oil, crude.....	920	265	4.0	1.7
Rape oil, refined.....	911	395°	4.9	2.0
Olive oil.....	914	245°	3.7	1.8
Castor oil.....	963	275°	16.4	3.0
Linseed oil.....	959	285°	3.2	1.7
Tallow.....	951	265°	5.2	2.5

—D. A. S.

#### *Mineral Lubricating Oils.* A. Kunkler. Dingl. Polyt. J. **274**, 323—328.

For the first portion of this article, see preceding abstract. From the considerations previously adduced, it appears that the ordinary method of judging the lubricating value of an oil from its specific gravity is untrustworthy, and does not permit the classification of oils from various sources as light, normal, and heavy oils. Even in conjunction with the flashing point, a separation into groups is not practicable in the case of American oils; with Russian oils a partial classification is possible. The experiments show that no direct relation exists between the viscosities and flashing points of oils, even from the same source. American and Russian oils may be distinguished by their behaviour on cooling. American oils all solidify at about 0° C., previously depositing solid paraffin and, in the case of clear samples, becoming turbid. Most Russian oils remain liquid down to about -10° C., and solidify to a clear transparent mass, without previous precipitation of paraffin. Cylinder oils contain, on an average, 23 per cent. by volume of substances boiling at 310° C.; whilst machine oils only contain 7 per cent. of these bodies. The variations in colour of the different oils is very slight. Dark oils exhibit a greenish fluorescence, and in thin layers appear blackish-brown and transparent. The paler shaft and machine oils of American origin generally possess a greenish fluorescence; whilst those of Russian origin have a bluish fluorescence. Pale Russian cylinder oils exhibit a blue shine, whilst the American oils have no fluorescence. American oils may be often distinguished by their superior purity as regards taste, smell, and colour. Pale Russian oils of 0.903 to 0.909 sp. gr., almost without exception, give a flocculent precipitate on standing; and many samples are not clear and possess a disagreeable sweet odour.

The temperature at which vapour is formed can only be approximately determined, and in conjunction with the flashing and burning points affords the means of judging the volatility of an oil, *i.e.*, its stability as a lubricant. Below are given the vapour evolution temperatures, the differences between these and the flashing points, and the differences between the flashing points and the burning points respectively, for two oils of each variety:—For Russian shaft oil, 105°—110°, 54°—62°, 26°—29°; for American, 110°—112°, 77°—80°, 40°—47°; for pale Russian machine oil, 120°—128°, 60°—75°, 37°—45°; for American, 125°, 81°, 39°; for

Russian cylinder oil, 110°—142°, 76°—108°, 27°—58°; for American, 185°—185°, 100°—103°, 53°—64°.

The determination of viscosity gives a means of dividing oils into groups according to their lubricative value. Oils possessing the same specific gravity, flashing point, &c., may yet differ considerably in viscosity. The probable source of an oil may be deduced from its viscosity and other data. Cylinder oils and dark machine oils of Russian origin exhibit with a higher flashing point and specific gravity, also a higher viscosity; whilst American oils possess with a higher viscosity and flashing point, a lower specific gravity. Pale Russian machine oils compared with American samples of the same flashing points and specific gravities, possess a distinctly higher viscosity. The German mineral oils from Alsace and Oelheim (Hanover) are similar to the Russian oils in so far that the viscosity increases with the specific gravity and flashing point. As regards their behaviour on cooling, they approximate more to American oils. Concerning the diminution of viscosity with increase of temperature, it is to be noted that between the temperatures 20°—50° C. and 50°—100° C. it is more rapid for Russian shaft and pale machine oils than for the corresponding American oils. On the other hand the viscosity of American cylinder oil diminishes more rapidly than that of Russian cylinder oil between the temperatures of 70°—100° C. and 100°—150° C. The diminution in viscosity is proportionately larger for cylinder oil between 70°—100° C.; and for shaft oil between 20°—50° C., than between 100°—150° C. and 50°—100° C. respectively. Several animal and vegetable oils used for lubricating purposes were examined. It was found that, with the exception of castor oil, they all had at 50° C., a smaller viscosity than mineral oil of the same or lower specific gravity. On the other hand there was a much less tendency to vaporisation, and, particularly at high temperatures, a smaller diminution in viscosity than in the case of mineral oils. Finally, the author describes some precautions to be observed in the determination of viscosity at different temperatures.—H. T. P.

#### PATENTS.

*Improvements in the Preparation or Manufacture of Petroleum for Domestic and other Purposes.* P. Smith and J. Pearson, Manchester. Eng. Pat. 3044, February 20, 1889. 8d.

This invention is for making solid or semi-solid petroleum or paraffin oils. After the oil has been deodorised by electrolysis, it is heated to 250° F., and 3 to 5 per cent. of powdered desiccated soap is stirred in, the temperature raised to 400° F. for a few minutes, and the product run into moulds to cool, when it solidifies.

The claim is made for the products and for the method of preparation.—D. A. S.

*Improved Cleansing, Scouring and Bleaching Compound for Wool and other Fabrics, also applicable to Cleansing Purposes generally.* A. H. Parker, London. Eng. Pat. 9410, June 6, 1889. 4d.

See under VI., page 174.

### XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

#### PATENTS.

*Improvements in or relating to the Manufacture of White Lead.* H. B. Condy, Battersea. Eng. Pat. 18,705, December 21, 1888. 6d.

LEAD suitably granulated is covered with dilute acetic acid, which is run off after 4 to 6 hours, and the lead left to oxidise by contact with air during another 4 to 6 hours. On covering the metal again with the dilute acetic acid, the oxide formed becomes dissolved and a fresh quantity is produced by running off the acid and further exposure to air. The treatment is continued until the solution of basic acetate of lead has acquired a specific gravity of 1.145, when it is treated in a separate vessel with carbonic acid. The carbonate of lead is separated in a filter and then suspended in water, to which sufficient alkaline carbonate is added to ensure precipitation of all soluble lead compounds. The white lead is finally filter-pressed and dried. Carbonic acid may be obtained by heating bicarbonate of soda, which yields the readily saleable carbonate as a by-product, or from well washed chimney gases. The liquor filtered from the washed white lead is evaporated for the recovery of the acetate of the alkali.—G. H. B.

*Improvements in the Manufacture of Paints and Pigments.* R. Stone, London. Eng. Pat. 1578, January 29, 1889. 4d.

THE "invention consists in novel methods of manufacturing paint for general purposes," "China clay, marble, spar, shale, partly matured river mud, Devonshire or Staffordshire clay, or any other substance of a fine or silky nature," being used for the body of the paint; one or more of these substances is then mixed with one or more of the following liquids:—petroleum oil, petroleum spirit, sulphuric acid, nitric acid or sodium silicate. After burning, the material is ground and mixed with oil and dryers, or with sodium silicate only in the usual manner. One ton of the clay or marble, &c. requires about 12 gallons of any of the liquids.—W. M.

*Improvements in and relating to Plastics, more especially designed for Imparting to Glue a Permanent Elasticity, and adapted to be used for various Purposes.* R. W. Johnson, New Brunswick, New Jersey, U.S.A. Eng. Pat. 18,503, November 19, 1889. 4d.

THE composition consists of glue or gelatin, glycerin, and sulpho-oleate of sodium or potassium. When the composition is to be used for printers' rollers, stoppers, &c. the proportions taken are: 1 lb. of glue and  $\frac{3}{4}$  lb. each of glycerin and sulpho-oleate of sodium or potassium. To prepare the compound, the glue is dissolved in as small a quantity of hot water as possible, the glycerin added, and the two thoroughly mixed. The sulpho-oleate is then added, and the mixture heated till all the water used to dissolve the glue has been driven off.

For many purposes the glycerin may be omitted, and the composition be made of 1 part of glue to  $1\frac{1}{2}$ —2 parts of sulpho-oleate of sodium. The composition may also be used as an ointment, in combination with vaselin or oil or other fat and suitable drugs.—B. H.

*A New Composition to be used as a Substitute for Ivory, and for other Purposes.* I. Appletree, Sheffield. Eng. Pat. 18,090, November 13, 1889. 4d.

THE material is composed of the following constituents:—granulated or pulverised ivory, 80 parts; isinglass, 20 parts; French chalk, 5 parts; water, 40 parts; gin, 2 parts; cotton wool, 2 parts. The mixture is placed in a boiler, heated, and constantly stirred for about 10 hours, until it assumes the consistency of paste. It is then removed from the

boiler, placed upon a cool slab, and subjected to a short process of rolling. The prepared paste is then put into a suitable mould or moulds, and subjected to great pressure. Instead of genuine ivory dust, that from walrus or similar teeth may be used, and for an inferior quality, the ivory may be substituted by bone of the kind now used for handles.—B. H.

### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

#### PATENTS.

*A New or Improved Machine for Extracting the Hair from Skins.* L. D. S. Cullin and G. Hughes, London. Eng. Pat. 16,545, November 14, 1888. 8d.

THIS invention relates to an improved machine for extracting the hair from skins. The skin is carried along on a band or web of leather or other suitable material, mounted on a frame, to which it is held by a clip, between two feeding rollers. The front end of the frame is provided with a roller of india-rubber, over which operates a helicoidal nipping and pulling device, furnished with four blunt knives, and revolving in a reverse direction to that of the india-rubber roller. A curved knife is mounted on the frame, and serves to raise the hair on its way to the pulling device. Drawings are given.—B. H.

*Improvements in or connected with Cylinders or Rotating Vessels for Use in Tanning or otherwise Treating Hides or Skins, Washing, Emulsifying, Churning, or like Operations, applicable also for the Treatment of Materials in Vacuo or under Fluid Pressure or the like.* B. Nicholson, South Norwood, and T. Palmer, Sevenoaks. Eng. Pat. 1345, January 24, 1889. 11d.

THE object of this invention is to provide cylinders or drums for use in treating hides or skins. The cylinder or drum is provided with hollow axles at one or both ends, through which a pipe, divided by a longitudinal partition into two passages, passes to the interior of the drum, through one of which passages air or other fluid pressure may be introduced or withdrawn, the other passage being employed for the introduction or withdrawal of the tanning or other liquor employed. The hides are supported in the drum by means of buttons carried on angled rods attached to lengths of tubing mounted on the tie-rods, which are connected to the opposite heads or ends of the drum.

For details, the drawings accompanying the specification must be consulted.—B. H.

*A New Process for "Discolouring" Tannic Acid Solutions.* H. J. Haddan, London. From J. Landini, Hamburg, Germany. Eng. Pat. 17,436, November 2, 1889. 4d.

THE object of this invention is to "discolour" tannin solutions, such as are used in tanneries, by treatment with nitrate of lead, afterwards adding alum and borax. The nitrate of lead solution is added to the boiling solution of tannin in small quantities at a time, and with continual agitation, till the "discolouring" is complete. The solution is then withdrawn, cooled down, neutralised, and filtered.

—B. H.

## XV.—AGRICULTURE, MANURES, Etc.

*On the Relation between the Physical Characteristics of Plants and the Richness of the Soil in Fertile Constituents.* G. Ville. *Compt. Rend.* **109**, 628—631. (Compare this Journal, 1890, 85.)

THE author wishes to determine the changes undergone by plants when the soil is deficient in some one of the four constituents necessary to vegetable life, viz., phosphate of lime, potash, lime, and nitrogenous matter. The characteristics studied are—

(1) Colour; (2) Height; (3) Total weight; (4) General appearance. The plant chosen as the type for experiment was hemp.

(1) *Colour*.—This subject has been dealt with in the former note, and the author only adds that the effects of change of nutrition on colour are generally most evident at some particular period of its development for each plant; for certain species the month following germination gives the maximum of contrast.

(2) *Height*.—A most important characteristic, affording a good criterion of the fertility of the soil. The height of each plant under similar conditions varies but little from one year to another if taken at the same period of each year. The same order of height is maintained throughout the year by plants under dissimilar conditions. With plants of which the nitrogenous matter is the most important constituent, the want of this matter makes the greatest difference in the height.

(3) *Weight*.—The weight of the crop in the dry state gives no less sure an indication than colour and height. The variations in absolute weight from one year to another of plants under the same treatment amount to from one

on two tenths; but as before, the relative order for plants under different treatment is the same.

(4) *General Appearance*.—Determined by photography.

A coloured plate is inserted in the text showing the photographs, the colour, height and weight of yield of hemp plants grown under different conditions in the year 1884.

	Height in Metres.	Weight of Yield in Kilogrammes.
Manure, "stimulating" (100 kilos. of nitrogen).....	1'53	11'220
Manure, "complete" (75 kilos. of nitrogen).....	1'20	11'150
Manure containing no nitrogen ..	0'61	4'740
Manure containing no phosphates	0'97	8'220
Manure containing no potash ....	0'40	5'220
Manure containing no lime.....	1'15	10'570
Soil without manure.....	0'18	2'175

The author has found that the amounts of carotene and chlorophyll in plants seem to be always proportional to one another, and afford a further criterion with regard to the nature and quantity of the fertile constituents contained in the soil.

It remains to be decided if the colour of chlorophyll solutions is proportional to their strength, as is the case with carotene. By a colorimetric method  $\frac{1}{10}$  milligramme of carotene can be estimated in its solution in bisulphide of carbon. [Carotene is extracted from the plant by petroleum ether, and after evaporation *in vacuo* the residue is redissolved in bisulphide of carbon to form an orange solution.]

### ESTIMATION OF CAROTENE (in milligrammes per 100 grms. of leaves) IN THE FOLLOWING PLANTS:—

	Plants in which the Nitrogenous Matter predominates.				Plants in which the Potash predominates.	
	Hemp.	Wheat.	Rape.	Betroot.	Potato.	Vine.
Manure, "stimulating" .....	350	195	183	183	204	..
Manure, "complete".....	315	167	..	164	173	200
Manure containing no nitrogen .....	199	74	114	120	159	177
Manure containing no phosphates .....	281	97	..	131	162	179
Manure containing no potash.....	254	104	..	140	124	125
Manure containing no lime.....	21	114	..	183	154	167
Soil without manure .....	250	66	..	143	94	121

The author hopes that farmers will adopt his plan of observing the four chief characteristics of plants to define the nature of their crops each year. He proposes to continue his researches on the estimation of carotene and chlorophyll.—P. J. H.

*On the Role of Ammonia in the Nutrition of the Higher Forms of Plant Life.* A. Müntz. *Compt. Rend.* **109**, 646—648.

THE object of this paper is to prove that plants can obtain their nitrogen directly from ammonium salts without these being first converted into nitrates.

Kühnmann at one time maintained that nitrates were always converted into ammonium salts (by means of

reducing actions going on in the soil) before they could yield their nitrogen to plants, and these views were held even after Boussingault had shown that nitrates are directly absorbable by plants.

At the present time the exactly opposite theory tends to prevail, and it is generally supposed that ammoniacal nitrogen must be converted into nitrate before it can be absorbed.

The difficulty of deciding as to the correctness of this theory lies in the presence of the nitrification ferment, which always converts a certain portion of the ammonium salt used as manure into nitrate.

The author has therefore devised the following means for growing plants on a soil in which the only nitrogen supplied as manure is in the form of sulphate of ammonia, all nitrification being prevented.

A certain quantity of natural soil was freed from nitrates by washing, manured with sulphate of ammonia, put into large pots, and then heated in an oven to 100°, a temperature amply sufficient to kill the nitrification ferment. To prevent future inoculation by the ferment the pots were placed in large cages partly closed in with glass and partly with cloths, which served to filter the air from all germs. The sides of the cage were smeared with glycerin, so that the arrangement was exactly similar to that devised by Tyndall.

The seeds were immersed for a short time in boiling water before being sown, so as to sterilise their surfaces. All these operations were performed in a closed room, of which the atmosphere had been purified by spraying with water, and then leaving the dust to settle. The cages containing the pots were put under an open shed, and were watered with sterilised water.

In order to have some means of comparison, another set of pots was prepared in exactly the same way, and these were then inoculated with the nitrification ferment by means of a minute quantity of compost.

Experiments carried out during the years 1885—88 gave identical results. No trace of nitrate was ever formed in the sterilised pots. Two examples are quoted in illustration. The results are given in milligrammes of nitric acid per kilogramme of earth.

Earth free from Nitrification Ferment.		Earth inoculated with Nitrification Ferment.	
Initial State.	Final State.	Initial State.	Final State.
Mgr. 0.0	Mgr. 0.0	Mgr. 0.0	Mgr. 91.2
0.0	0.0	0.0	420.0

The growth of the plants was as a rule satisfactory, maize, the bean, kidney bean, and hemp attaining a height of over 1 metre.

By determining the proportion of nitrogen in specimens of the plant, and subtracting the amount present in the seed, the total quantity directly absorbed in the form of ammoniacal nitrogen could be determined. The following examples are quoted:—

	Nitrogen		
	In the Seed.	In the Plant.	Derived from Ammonium Salt.
Bean.....	37	956	915
Kidney bean....	16	105	89
Maize.....	3	211	208
Barley.....	7	50	49.3
Hemp.....	5	115	114.5

These experiments prove conclusively that the higher plants are capable of absorbing ammoniacal nitrogen directly by means of their roots, and hence that the nitrification of ammonia manures is not an indispensable condition for their being utilised.—P. J. H.

#### *The Artificial Manure Manufacture.* W. Cohn. Chem. Ind. 12, 459—461.

As the author predicted two years ago (Chem. Ind. 10, 444), the successful use of the cheaper potash salts and Thomas phosphate powder has been accompanied by an increase in the use of artificial manures generally. In 1888, 3,508,450 centner (about 173,650 tons) of Chili saltpetre was imported into Hamburg; in 1887 the imports of this article had been as much as 5,084,850 centner (250,325 tons); and in 1889 the imports had again increased over 1888; at the beginning of September the amount was 4,427,900 centner (217,896 tons).

The use of sulphate of ammonia has increased in like manner, and renewed efforts have been made to collect the ammonia formed in the process of coke-burning, efforts which are becoming more and more successful. Maercker has recently (Dent. landw. gesell. Mittheil. 11, 1889—1890) published the results of experiments on the effect of nitrate of soda and sulphate of ammonia when used both in small and large quantities for corn, beetroot, and potato crops, which show that ammonium sulphate has at least an equal value to the sodium nitrate. In the case of superphosphates an improvement in the process of manufacture is hardly looked for. In the price, however, such an improvement has been realised, the manufacturers having combined together to obtain a proper remuneration for capital invested. Bone meals, both raw and boiled, continue to hold the position they have attained, the steamed bone being more and more sought after. At the recent annual meeting of the Deutsche Versuchs-Stationen at Speyer the question of adulteration of bone meals was fully discussed and a definition of what bone meal should be was arrived at. The property of absorbing ammonia said to be possessed by gypsum formed in the manufacture of superphosphates, has encouraged several manufacturers to introduce this waste material into the market.—J. W. L.

#### PATENTS.

*Improvements in the Means or Method of Treating or Preparing certain Refuse Matter to increase its Fertilising Properties.* W. Riddiough, Bradford. Eng. Pat. 1710, January 31, 1889. 4d.

The improvement consists in grinding or crushing "night-soil," whereby its activity and value as a manure are increased.—E. J. B.

*A Compound of Animal Substances and Earths containing Phosphate of Iron or Alumina for Fertilising Purposes.* N. B. Powter, New York, U.S.A. Eng. Pat. 14,633, September 17, 1889. 4d.

The fertilising compound is formed by mixing some powdered phosphatic rock containing alumina or iron, such as Redonda phosphate, with acid and wet animal matter such as undried meat, skin, blood, hair, animal filth, &c.

—E. J. B.

*A New or Improved Insecticide for the Treatment of the Diseases of the Vine and other Trees and Plants.* J. B. Alzugaray, Porto, Portugal. Eng. Pat. 15,539, October 3, 1889. 4d.

This insecticide, entitled "Phylloxerine or Anti-phylloxerine Liquor," consists of a mixture of petroleum, shale or tar oils, with sulphur or sulphides of calcium or sodium.

—D. A. S.

*Improvements in Fertilisers.* E. and H. Saxl, Vienna, Austria. Eng. Pat. 18,918, November 25, 1889. 4d.

This invention consists in drying and then pressing into cakes the excrements of domestic animals, in which form the material can be easily and cheaply transported. The cakes may be ground and reduced to powder of any required degree of fineness.—W. M.

## XVI.—SUGAR, STARCH, GUM, Etc.

*New Relation between Sugars and Furfuryl Derivatives. Constitution of Methylfurfural and Isodulcitol.* Maquenne. *Compt. Rend.* **109**, 603—606.

THE author has shown (this Journal, 1889, 974) that *fucus* when distilled with dilute sulphuric acid yields furfural and methylfurfural. There are four possible formulæ for this latter, one in which a  $\text{CH}_2$  group is introduced into the side chain, and the other three in which a  $\text{CH}_3$  group is attached to one of the carbon atoms of the ring, thus displacing a hydrogen atom. It yields acetic acid on oxidation, and so it must be one of these latter.

Isodulcitol distilled with four times its weight of sulphuric acid  $15^\circ\text{--}20^\circ\text{B.}$ , yields a methylfurfural identical with that obtained as above, together with small quantities of acetone, but not a trace of furfural. Fischer and Tafel have shown that isodulcitol is an aldehyde of normal hexane, and Herzig found that it yielded acetic acid on oxidation, showing that it contained a methyl group at the extremity of the chain. The production of methylfurfural from isodulcitol must be brought about by joining the chain so that this methylfurfural must be represented by the formula—

As arabinose yields, by similar treatment, furfural, isodulcitol may be considered as  $\omega$ -methylarabinose.

Although the yield of methylfurfural from isodulcitol is small, yet its production may be employed as a test when it is not possible to crystallise the sugar.

On distilling a quantity of any body containing isodulcitol with sulphuric acid ( $20^\circ\text{B.}$ ), the less volatile portion of the oily distillate gives a green colouration with alcohol and sulphuric acid, which is characteristic of methylfurfural.

—A. L. S.

*On the Fermentation of Raffinose in Presence of different Kinds of Yeast.* D. Loisean. *Compt. Rend.* **109**, 614—615.

THE author gives extracts from a sealed paper deposited by him with the Academy in March 1888, which contains an account of similar experiments to those described recently by Berthelot (this Journal, 1889, 933), showing that raffinose under the influence of a weak yeast yields a glucose and saccharose, the former of which only ferments.

—A. L. S.

*On Two New Sugars from Quebracho Bark.* G. Tanret. *Compt. Rend.* **109**, 908—910.

COARSELY powdered quebracho-bark (*Aspidosperma quebracho*) is mixed with milk of lime and lixiviated with 50 per cent. alcohol. The solution is reduced by distillation and evaporation to a bulk of 500 cc. per kilo. of bark used, neutralised with acetic acid and treated with "Extract of Saturn." From the filtered liquid the sugar is precipitated by means of ammoniacal lead acetate. The lead precipitate is decomposed with dilute sulphuric acid, the solution is concentrated to a syrup, and then dissolved in the least possible quantity of 90 per cent. alcohol. Ether is now added, which precipitates a sticky mass. The precipitate is redissolved in water, concentrated and left in a cool place for several days, when fine crystals separate. The crystals are washed with a little dilute alcohol, dissolved in water and decolourised by means of animal charcoal. The concentrated solution is dissolved in boiling 60 per cent. alcohol, which on concentration deposits crystals of the new sugar. The yield is about 1 grm. per kilo. of bark used. The author names this sugar *Quebrachite*. Its

formula is  $\text{C}_7\text{H}_{14}\text{O}_6$ . It crystallises in anhydrous rhombic prisms, and is very sweet to the taste. It is very soluble in water, and pretty soluble in boiling alcohol, even when absolute, but insoluble in ether. Its density is 1.54. It melts at  $186^\circ\text{--}187^\circ\text{C.}$  and boils in vacuo at about  $210^\circ\text{C.}$ , at the same time subliming in beautiful needles. It is levo-rotary,  $(\alpha)_D = -80^\circ$ .

Quebrachite is only fermentable under the action of beer-yeast. It has no action on Fehling's solution, but reduces ammoniacal silver nitrate in the cold. Boiling dilute solutions of acids and alkalis appear to have no effect on it. It is not precipitated by basic acetate of lead, but only by ammoniacal lead acetate. Strong sulphuric acid dissolves it very slowly at ordinary temperatures with but little colouration; but at  $100^\circ\text{C.}$  it dissolves more quickly, quebracho-sulphuric acid being formed. This acid is levo-rotary and forms soluble in crystallisable calcium and barium salts. Quebrachite yields an acetic ether melting at  $89^\circ\text{C.}$ , and also a very unstable nitro-derivative, both of these compounds are levo-rotary. Heated with hydriodic acid, quebrachite forms methyl iodide and a new inosite, thus:—

This body crystallises in brilliant prismatic needles, containing two molecules of water of crystallisation, which it loses rapidly on exposure to air. The author names it "*Levo-inosite*." It is soluble in 2.3 parts of water at  $12^\circ\text{C.}$ , slightly soluble in boiling alcohol, but insoluble in ether. It melts at  $238^\circ\text{C.}$ , and boils in vacuo at  $250^\circ\text{C.}$  with volatilisation, being, however, less volatile than quebrachite. Its rotary power,  $(\alpha)_D$ , is  $-55^\circ$ .—H. T. P.

*Advances in the Manufacture of Starch, Dextrin, Glucose, &c.* Dingl. Polyt. J. **274**, 328—334.

THE combined grater and grinding mill used in the manufacture of potato starch seems to have no mean rival in the shape of H. Schmidt's *compound-grater* (Ger. Pat. 45,284). O. Saare (Zeits. f. Spiritusind. **12**, No. 24) publishes the results of a number of comparative trials made with the two forms of apparatus at H. Schmidt's experimental works. The compound-grater employed consisted of a mantle of perforated sheet-iron surrounding the inner rasping drum. The mantle was grated alternately inside and outside by striking the perforations alternately from the outside and inside respectively. The whole apparatus was so arranged that the compound-grater could be fixed in its place or removed with very little trouble. The rasping drum had a diameter of 400 mm., and was provided with new gratings having 18 teeth to the inch. Four experiments were made, 10 kilos. of washed and superficially dried potatoes being used each time. The potatoes contained 17.7—17.9 per cent. of starch. The rate of grinding was the same in each case. The ground potatoes and washings were collected in a barrel and filtered through two sieves, the second being the finer of the two. The milky filtrate was allowed to settle for a day in another barrel, when the starch was separated, dried, and weighed. The pulp remaining on the sieves was also dried and weighed, and the starch left in it estimated. The first experiment was made with a carefully-mounted rasping drum without the compound-grater; the second was made with a well-set drum fitted with the compound apparatus. The third and fourth experiments were made with a badly-fitted-up rasping drum, provided without and with the compound-grater respectively. The results obtained are given below. In the first experiment there were obtained 395.5 grms. of pulp and 1,521.9 grms. of starch; in the second trial 356.3 grms. of pulp and 1,563 grms. of starch. Further, in the first case, the pulp contained 264 grms. of bound starch, and, in the second case, 223 grms. of bound starch. The third experiment yielded 446.5 grms. of coarse and 42.8 grms. of fine pulp, and 1,428.4 grms. of starch. The fourth trial gave 346.1 grms. of coarse and 46.3 grms. of fine pulp, and 1,532.5 grms. of starch. These results show that the compound-grater compensates for the defects of a badly-mounted rasping drum, and raises the yield of starch on a level with that obtained by means of a first-class

resp. As regards the extra power required on addition of the compound-grater, experiments show it to be 1.2 indicated horse-power, whilst a grinding mill requires 1.5—2 horse-power. Saare condemns the use of centrifugal machines in damp-starch factories, chiefly on economical grounds; besides which centrifugal starch is said to become mouldy very readily.—H. T. P.

## XVII.—BREWING, WINES, SPIRITS, Etc.

### PATENTS.

*Improvements in the Treatment of Commercial Alcohol.*  
H. E. Sorel, Paris, France. Eng. Pat. 17,338, November 28, 1888. 11d.

In this invention the following two operations are carried on concurrently:—

- (1.) Partial and successive distillations of concentrated products.
- (2.) Partial and successive condensations at high temperature.

These two operations follow from the same physical law, which may be stated:—There exists for each volatile body, and for each temperature, in the presence of a given solvent which does not act chemically on the body when brought to the same temperature, a definite and fixed relation between the quantity of body existing in the form of vapour in a certain weight of vapour in contact with the liquid, and the quantity of the same body dissolved in the same weight of the liquid. This relation is defined as the *partage coefficient*. When the partage coefficients of a volatile liquid and its solvent are very nearly equal, it is impossible to separate them by distillation.

Now, by so arranging the strength of the alcoholic liquid to be treated, the temperature of distillation can be varied between 79° and 100° C., and so the relative partage coefficients may be altered as desired.

Under the conditions under which the invention is worked, alcohol of such a concentration is used that one-half or two-thirds of the alcohol may be distilled off without materially altering the boiling point.

Employing a continuous distillation column, the walls of which are protected from radiation, and passing into it at the top alcohol, between 90° and 70° Gay-Lussac, previously raised to its boiling point, the alcohol passing from shelf to shelf to the boiler at the bottom, the inventor has verified the following relation:—

$$S_1 = S_m \left\{ 1 + \frac{\left( \frac{Kp}{P} \right)^{m-1} - 1}{\frac{Kp}{P} - 1} \right\}.$$

between  $S_1$  = the proportion of a certain impurity existing in a state of solution in the liquid of the first upper shelf, and  $S_m$  = the proportion of the same impurity in the liquid of  $m^{\text{th}}$  shelf,  $K$  being the partage coefficient for the liquid and  $P$  being the proportion of this impurity in the vapours passing from bottom to top to that in the liquid passing from top to bottom.

The inventor has verified this in practice, and finds that he obtains under the above conditions all the impurities having a partage coefficient greater than unity in the products of distillation, whilst those having a partage coefficient less than unity are obtained in the non-distilled alcohol.

It must be noted that in this case the distillation column does not work as an ordinary distillation column because there is not, so to speak, any expenditure of liquid until it arrives in the vaporising boiler. The vapour traverses all the shelves without notable condensation, and the proportion between the amount of vapour and liquid remains approximately constant.

The vapour escaping from the top of the distillation column, and containing, as above stated, only those impurities having a partage coefficient greater than unity, are either passed into an ordinary distillation column worked in the usual way or into the partial condensers. These consist of a series of tubes of elliptical section arranged so that the liquid condensed in each series may be collected separately. They are immersed in water contained in a series of tanks, the temperature of the one containing the condenser into which the vapours first pass is kept at 77°—79° C., and the temperature of each succeeding one a few degrees lower until the last one, which is kept cold.

The inventor even finds it advantageous to so arrange the heating of the tanks that the bottom of one is kept at the same temperature as the top of the next, the temperature gradually rising from the bottom to the top of each tank and he separates the series of condensers contained in each tank into elements, each element consisting of one horizontal layer of pipe, and the liquid from each element is collected separately.

The products condensed at a low temperature, and containing a large quantity of volatile products, are treated with oxide of lead, or plumbate of soda or potash. As there is some difficulty in separating the lead by filtration, he adds some such neutral salts as chloride of magnesium or manganese, soluble in alcohol, and capable of forming a flocculent precipitate with the alkaline earths or their carbonates.

One of these chlorides is added to the liquid containing the lead and then milk of lime or some similar substance, when a flocculent precipitate is formed which rapidly settles, taking the lead with it. The clear liquid may now be distilled.

The claims are:—

“1. Partial distillation in a continuous distillation column of the crude phlegms or alcohols in course of manufacture more or less diluted with water, so as to separate these phlegms or alcohols into vaporised products containing principally the more volatile constituents of the mixture, and non-vaporised products containing principally the less volatile constituents.

“2. Application to distilling apparatus and to rectifiers, of condensers forming series, each maintained at a constant temperature, each condenser of each series having its separate outlet.

“3. Successive additions to the crude phlegms or alcohols in course of treatment of a composition of oxide of lead, then of a salt soluble in alcohol and capable of being precipitated in flakes by magnesia, lime, the alkalis or the alkaline carbonates, and, finally, one of these reagents; this succession of chemical operations having for its object the combination into a filterable precipitate, of a part of the ethers and analogous bodies.”—A. L. S.

*Improved Process for Aërating and Purifying Beer Worts and Apparatus therefor.* O. Imray, London. From A. Bergh, Copenhagen, Denmark. Eng. Pat. 86, January 2, 1889. 8d.

In order to effect the cooling and aërating of wort in a sterile condition, the hot wort is led into a rotating centrifugal machine which is contained in a closed case. From this the wort is taken by a pipe, whose inlet is placed just below the rim of the machine, into some convenient closed cooling apparatus and thence to the fermenting vessels. The wort is free from grounds as these remain behind in the centrifugal machine. Air is admitted into the case surrounding the centrifugal machine through a cotton-wool filter and the whole apparatus is sterilised by steam before use.

The centrifugal machine is also useful for removing the yeast remaining when fermentation has proceeded as far as necessary, the after-fermentation being brought about by the introduction of a suitable quantity of some pure ferment.—A. L. S.

*A Vinegar Generator and Filter.* R. H. Herder, Chicago, U.S.A. Eng. Pat. 570, January 11, 1889. 8d.

THIS patent has for its object the more speedy acetification of the mash and the filtration of the product. The apparatus consists of a cask hung on trunnions so as to swing in a vertical position. At one end of the cask are fitted three perforated false bottoms, the space between the two nearest the head of the cask is filled with some filtering material, such as sand, charcoal, &c. Bungholes and stoppers are inserted where necessary. The interior between the inside false bottom and the opposite head is filled with wood shavings. Four check-valves for admitting air are inserted, one in each head and the other two in the side of the cask about two-fifths of the length of the cask from each end, and they are so arranged that the two lower ones are always closed and the two upper ones open. The cask is half filled from the top with a suitable fermented or distilled mash. Acetification takes place rapidly in the upper part, where a certain amount of liquid adheres to the shavings, the air finding its way in through the check-valves. After four hours or so the cask is inverted and acetification takes place in the other half of the cask, the other pair of check-valves coming into operation, and so on until the acetification is completed, when the vinegar is run out through the filter at the bottom of the cask.

—A. L. S.

*Improvements in the Treatment of Commercial Alcohols.* H. E. Sorel, Paris, France. Eng. Pat. 770, January 15, 1889. 8d.

ACCORDING to the formula given in Eng. Pat. 17,338 of 1888 (see previous page) for determining the ratio between the impurities on an upper stage of the column to the impurities on a lower stage, *i.e.*, the velocity of conveyance of impurities from the bottom to the top of the column, it is seen that this ratio is not dependent on the term  $K, p, P$ , taken separately, but on the ratio  $K \frac{P}{p}$ . The inventor has

found by experiment that the ratio  $\frac{P}{p}$  is almost independent of the absolute value of the reflux returning from the top of the column, but depends essentially on the temperature; being low, between 95° and 100° C., increasing very rapidly to 80°—82° C., and then decreasing rapidly; whilst as the temperature falls  $K$  diminishes. On the whole the ratio  $K \frac{P}{p}$  increases from 90° to 80—82° C., and then decreases very rapidly to 78·7° C., the boiling point of strong alcohol. So, the lower the temperature of the lower stages of the rectification column, the better will the tail products be retained, as the term  $K \frac{P}{p}$  is then kept as small as possible.

It may also be noted from the above considerations that the stage where the temperature of the column ranges from 80°—81° C. serves to mark off the part where the tail products are constantly returned and turned back towards the bottom, and that part where they tend to rise faster than the alcohol; so that it is advantageous to be able to separate the vapours condensing at this stage from the rest.

In putting these considerations into practice the inventor reduces the functions of the analyser to simply maintaining the temperature of the vapours at the proper point, and so create as little reflux as possible. The portion of the column which is not refrigerated is surrounded with some non-conducting covering.

The vapours enter at the bottom of the column, passing over the surface of the return liquids; they then rise into the regulating refrigerator which consists of two sections. The lower one is filled with a number of hollow earthenware cylinders, open top and bottom, and arranged in quincunx form, one above the other in horizontal stages. The upper section contains several horizontal series of copper tubes, traversed by hot water from the analyser, the tubes being placed very close together and their surfaces plaited and undulated, so as to distribute the condensed liquid as regularly as possible over the cylinders of the lower stage.

Between these two sections the temperature is 80°—81° C., the stage at which it is pointed out above the tail products tend to accumulate, and an arrangement is inserted for separating off at will the liquid condensing here.

The vapours then enter the rectifying column properly so called, which consists of two sections of similar construction to those forming the regulating refrigerator, except that the one filled with the earthenware cylinders is longer. The vapours issuing from the top of the column are either passed into an ordinary refrigerator or some such arrangement as is described in the abstract above referred to.

The claims are:—

"1. The improvement in rectification or dephlegmation columns for the treatment of commercial alcohols consisting in adapting at the lower part thereof a refrigerating apparatus.

"2. In combination with refrigerating apparatus applied as aforesaid, provision for the continuous withdrawal of impure alcohol.

"3. The method of and the apparatus for the treatment of commercial alcohols."—A. L. S.

*Improved Alcoholic Beverages.* A. Malzy, London. Eng. Pat. 962, January 18, 1889. 4d.

THE invention consists in the preparation of mixtures of alcoholic liquids and aerated or other waters in definite proportions, having regard to quantity and quality, in vessels so that the liquid can be easily and quickly retailed ready mixed. The process of mixing can be effected before, during, or after aeration. (Compare this Journal, 1887, 221.)

—A. L. S.

*Improvements in Apparatus for promoting Circulation and Aeration of Brewer Worts.* G. G. Cave, Fenny Stratford, and J. H. Howell, Bristol. Eng. Pat. 1942, February 4, 1889. 6d.

TWO "steam boiling coppers" are employed, they are placed side by side, and are surmounted by a "curb" or pan which extends over both vessels, communication being maintained between the bottom of the coppers by a pipe. The wort in one of the coppers is maintained at a higher temperature than the other, and consequently in boiling overflows and is conducted by the "curb" into the other copper, whilst an equal quantity passes by the pipe into the first copper, thus maintaining a constant circulation. A second pipe provided with a valve connects the coppers just below the curb, so that when, owing to evaporation, the contents of the first copper do not overflow into the second, the circulation may still be kept up by opening up this pipe. Instead of using two coppers the low-temperature one may be replaced by a vat or other vessel of copper or any other suitable material.—A. L. S.

*Improvements in Shavings for Vinegar Generators and for Clarifying Beer.* R. H. Herder, Chicago, U.S.A. Eng. Pat. 3362, February 25, 1889. 8d.

THE improvements consist in the production of shavings to be used in the manufacture of vinegar, &c., which shall expose more surface than the ordinary flat coiled shaving.

To this end the shavings are planed with transverse or longitudinal ribs, with corrugations, serrations, or any combination of these. In this way there remain, when the shavings are coiled, channels between the coils formed by the ribs, &c., through which the wort and air may pass. The patentee claims that the wort takes much longer to trickle over these shavings, thus exposing it a much longer time to the atmosphere and thereby increasing the working capacity of the generator.—A. L. S.

*Improvements in or relating to the Preservation of Beer and the like.* A. J. Boulton, London. From H. F. L. Otto and G. B. Schwerdtfeger, Doebeln, Saxony. Eng. Pat. 15,401, October 1, 1889. 4d.

THE inventors coat the interior of the cask with paraffin wax which has been impregnated with salicylic acid, which they state prevent the entrance of all organisms from the exterior air into the beer.—A. L. S.

*A New or Improved Pasteurising Apparatus.* W. A. Vollmer, Apenrade, Germany. Eng. Pat. 15,810, October 8, 1889. 6d.

THIS apparatus is for the pasteurising of beer in bulk. It consists of an air-tight vessel surrounded on all sides except the front by a water-jacket, the temperature of which may be raised or lowered by passing steam or cold water through a coil contained in it. Two thermometers, a manometer, a gauge for determining the level of the liquid, a safety-valve, and manhole are attached to the front of the vessel.

The apparatus is filled with beer and the temperature raised by the steam coil to 60° F. and kept constant for some little time, and then by replacing the steam by cold water the beer is cooled until the manometer indicates the normal pressure.—A. L. S.

*Improvements in the Treatment of Brewers' Grains for Cattle Food.* C. P. Goode, London. Eng. Pat. 16,325, October 16, 1889. 4d.

THE dried grains, whilst still hot, are subjected to great pressure in a mould divided into compartments; by this treatment the grains adhere and when cooled form dry coherent cakes suited for transport. When the grains to be treated are cold, they must be heated in the mould. In some cases other nutritious matters are added to the grains before compression.—A. L. S.

*Improvements in Treating and Rectifying or Ayeing Alcohol or Alcoholic Liquors or the like by Electricity.* A. de Meritens, Paris, France. Eng. Pat. 16,917, October 26, 1889. 4d.

THE present patent has reference to Eng. Pat. 13,293 of 1888 (this Journal, 1888, 860). The inventor states that alternating electric currents assist chemical combination between bodies which are in a condition to combine; and that ammonia, aniline, the phenylene diamines, &c., which will combine with the aldehydes at 80° to 100° C. combine at ordinary temperatures with the help of an alternating current. He therefore adds to the alcoholic liquor two equivalents of ammonia or aniline, &c., to each equivalent of aldehyde to be combined, and passes an alternating current, when combination and consequent neutralisation immediately take place.—E. T.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

### (A)—CHEMISTRY OF FOOD.

*Foods and Food Adulterants.* Investigations made under direction of Dr. H. W. Wiley, Chief Chemist. Part Fifth. *Baking Powders.* C. A. Crampton, Assistant Chemist, United States Department of Agriculture; Division of Chemistry; Bulletin 13, 1889, 557—627.

NO recognised standard for the composition of a baking powder exists, and as long therefore as no injurious ingredients are present in such a powder it cannot properly be looked upon as adulterated, whatever its composition. In a case like this, therefore, of a food adjunct, the composition of which is to a certain extent arbitrary, it is desirable that the public should be in possession of data which will enable it to form some opinion as to the relative value of a baking powder. At present the sale of baking powders is not regulated, but it seems desirable that manufacturers should be required by law to use a label giving approximately the composition or analysis of the powder sold. Some regulation of this sort seems only fair to the consumer and the manufacturers of a first-class and therefore high-priced article.

The bulletin under consideration is a step in the right direction, for before useful legislation can be carried out on a matter like this, it is necessary that analytical data should be carefully collected and discussed.

The oldest, and in a sense the best method of leavening bread is by means of yeast. By its means the carbohydrates of the flour are partially decomposed, and the carbonic acid evolved in the process lightens or "leavens" the dough. Excepting the yeast no foreign materials are introduced into the bread, but the process is a slow one, and the road has therefore been paved for the introduction of mechanical and chemical methods to accomplish the aëration, or charging of the dough with gas, more rapidly. One advantage of yeast-raised bread is that the albuminoids get peptonised. In Dauglish's method of aërating, the dough is made in a closed vessel, with water charged with carbonic acid under pressure. When the pressure is relieved the expansion of the gas leavens the bread. A weak wort, in which fermentation has set in, and which absorbs the carbonic acid gas more readily, is also used instead of water. The above method of leavening is therefore largely a mechanical one.

No reliable data exist with regard to the consumption of baking powders; there seems, however, some ground for believing that some 25,000,000 lbs. are paid annually for baking powders by consumers in the United States. Baking powders consist essentially of an alkaline carbonate—bicarbonate of soda is almost exclusively used for this, sometimes bicarbonate of ammonia—mixed with a solid acid or acid salt. Usually some dry inert material, such as starch, is added to prevent action between the chemicals during the time the powder is kept. This is called the "filling."

Baking powders can be broadly and conveniently classified according to their acid constituents:—

- (1.) Tartrate powders.
- (2.) Phosphate powders.
- (3.) Alum powders.

Many powders are mixtures of at least two of these three classes.

*Tartrate Powders.*—In these bitartrate of potassium or "cream of tartar" is usually employed to supply the acid. Sometimes free tartaric acid is used. The reaction brought about on the addition of water to dissolve the constituents would be—

The products of the reaction are therefore potassium, sodium tartrate (Rochelle salt), carbon dioxide and water.

With free tartaric acid the reaction is—

Here the products of the reaction are sodium tartrate and carbon dioxide. Both sodium tartrate and Rochelle salt are slight purgatives. The quantity of Rochelle salt present in a loaf of bread (2 teaspoonfuls of powder to a quart of flour) is probably somewhat more than would be contained in a scidlitz powder. In other respects these salts are harmless, and the tartrate baking powders may on the whole be looked upon as the most satisfactory class of baking powders. Tartrate powders prepared with free tartaric acid probably do not keep so well as those in which the bitartrate of potash is used, hence the latter class is almost invariably met with.

*Phosphate Powders.*—In these monocalcium phosphate is the acid salt employed. It is difficult, however, to obtain this salt pure, and most phosphate powders therefore contain a considerable amount of sulphate of lime. The following equation, probably, fairly well represents the reaction which takes place with these powders:—

The phosphate of soda is a mild purgative, but otherwise, no particular objection can be raised to these powders, and perhaps, in cases of malnutrition, scrofula, rickets, phthisis, &c., the presence of phosphates may be advantageous. Acid phosphate of soda is said to have been used in former years as a constituent of baking powders, but appears to have been entirely superseded by the lime salt.

**Alum Powders.**—In these the salt used in place of an acid is either potash alum ( $K_2Al_2(SO_4)_4 \cdot 24 H_2O$ ), or ammonia alum ( $(NH_4)_2Al_2(SO_4)_4 \cdot 24 H_2O$ ) according to their relative cheapness. At present the ammonia alum is exclusively used. As burnt alum, *i.e.*, alum deprived of its water of crystallization, dissolves more slowly in water; it is probably in this condition that it is used for baking powders. The reaction would be—

The residue therefore consists of sulphate of soda, ammonium sulphate and alumina. Sodium sulphate is a slight aperient. Little is known about the physiological action of ammonium sulphate. With regard to the alumina the following conclusions are drawn :

- (a.) It must be expected that small quantities, at least, of alum will be absorbed by the digestive fluids, where any form of powder containing it is used.
- (b.) Whether the absorption of small quantities of alum into the human system would be productive of serious effects is still an open question, and one that careful physiological experiments alone can decide.
- (c.) That form of alum powder in which sufficient phosphate is added to combine with all the aluminium present is a better form, and less apt to bring alum into the system than where alum alone is used.

Most American alum powders are of this latter description. There are few "straight" alum powders, *i.e.*, alum powders containing alum only as the salt which reacts with the carbonate.

In England and France, which have food adulteration laws, the use of alum in bread-making is prohibited.

Sometimes tartaric acid or bitartrate is added to alum powders. This practice is objectionable, as the acid tends to prevent the precipitation of the aluminium hydrate and facilitates the absorption of alumina into the system.

Conclusion (c.) above has reference to the mixed alum and phosphate baking powders. In this case the character of an alum powder would, it seems, be improved. The reaction would be—

and, as will be seen, insoluble calcium sulphate partially replaces sodium sulphate, and the less soluble aluminium phosphate will to a greater or less extent replace alumina.

The following comparison of the different classes of powders is then given: "It is assumed, of course, that the ingredients are combined in exactly the proper proportions, and that all the chemicals used are of full purity and strength.

Powders.	Carbon	Total Residue
	Dioxide.	of the Weight
	Per Cent.	of Chemicals
		used.
Tartrate .....	16	104
Phosphate .....	22	123
Alum .....	27	128
Alum and phosphate .....	17	111

"From this it will be seen that a tartrate powder, theoretically, gives the lowest percentage of carbonic acid gas in proportion to the weight of chemicals used in its composition, together with the least weight of residue. It is assumed that burnt alum is used in both the alum and the alum and phosphate powders. The residues are calculated to hydrated salts in all cases. No account is made of inert "filling," as that would be the same in each case. It should, of course, be remembered that in the above calculation the *total weight* of residue is reckoned in each case without regard to solubility or relative effect upon the system of the various salts formed."

Carbonate of ammonia is sometimes used alone by bakers as a chemical aerating agent. If it were entirely driven off during the baking of the bread there would be no objection to its use. But that this is the case is open to doubt, and it is not therefore advisable to use it alone in baking. An objection can hardly, however, be raised to the small quantities of this substance present in some baking powders.

Then follow analyses of banking powders found in the market and their discussion by Professor H. A. Weber, forming part of the annual report of the Ohio State Dairy and Food Commissioners for 1887. The discussion does not add materially to what has been said so far, and the analyses of 30 samples cannot, of course, be given. Of these, Mr. Crampton says: "Professor Weber's analyses are rather superficial and incomplete, probably being made under conditions that did not admit of thorough quantitative work. He has overlooked entirely, for instance, the fact of the presence of phosphoric acid in many alum powders."

Professor H. B. Cornwall, in his "Report of the Dairy Commissioner of New Jersey, 1888," p. 82, gives the results of the examination of a large number of baking powders, but excepting for the "strength," *i.e.*, the yield of carbon dioxide which was estimated quantitatively, the examination was merely of a qualitative nature.

Sulphates, ammonium salts, phosphates, alumina, tartaric acid and tartrates, and potash were tested for, and the results enabled him to classify the powders into—

1. Cream of tartar powders.
2. Acid phosphate of lime powders.
3. Alum and phosphate powders.
4. Alum powders.
5. Unclassed powders.

Professor Cornwall's conclusions agree with those already given at the beginning of this abstract.

We now come to a consideration of the analyses of the United States Department of Agriculture. The samples examined were purchased at retail stores in Washington, D.C.

For classifying the samples, qualitative analyses, similar to those used by Professor Cornwall, were employed.

A detailed description of the quantitative methods employed would take up too much space; suffice it to say that for the carbon dioxide two determinations were always made, one with the addition of acid for determining the *total* amount of carbon dioxide present, the other with the addition of water only for determining the amount of *available* carbon dioxide present, *i.e.*, the carbon dioxide actually liberated when the powder is used for baking purposes.

Other ingredients subjected to quantitative analysis were—

Starch (present as filling).  
Phosphoric acid.  
Tartaric acid.  
Alkalis.  
Aluminium.  
Calcium.  
Sulphuric acid.  
Ammonia.  
Moisture.

The results of each analysis are given in the first instance as acid and basic radicals in percentage composition. An attempt is then made to combine these into salts showing the constitution of the powder. In the latter case, however, the results arrived at are at best but approximately correct, for the difficulties in the way of arriving at the true constitution of a powder are very great, if not insurmountable. The analyses agree fairly well in a general way with those obtained by Professors Weber and Cornwall. The value of a baking powder with regard to its available carbon dioxide diminishes with age, so that the results obtained cannot strictly be taken as showing the relative values of the powders; but, generally speaking, the tartrate and phosphate powders give higher percentages of carbon dioxide than the alum and alum and phosphate powders. Mr. Crampton says: "Professor Cornwall's average for 20 samples of alum and phosphate powders (no straight powders included) is 8.97 per cent.; for eight samples of tartrate powders, 11.60. Professor Weber's average for 19 samples of alum powders is 7.58 per cent.; for eight samples of tartrate

powders, 11.20 per cent. My average for 20 samples of both alum and alum and phosphate powders is 8 per cent.; for eight samples of tartrate powders, 10.10 per cent. The only straight phosphate powders sold seem to be the various preparations made by the Rumford Chemical Works, and the 'Wheat' powder; at least these are all obtained by any of the investigators. The carbonic acid strength of the former is uniformly good, slightly higher than the tartrate powders; the latter is a peculiar preparation, made up without any filling whatever, and gives a low percentage of carbonic acid, except in one of Professor Cornwall's samples, which seems to have been obtained quite fresh."

A point of importance in connexion with baking powders is the percentage of filling or inert material they contain. The object of the filling is mainly to prevent the active constituents in the powder from reacting on each other during the time the powder is kept. It is possible that too much or too little filling may be present in a powder. In the former case the value of a powder is diminished by the presence of too large a proportion of inert material. In the latter case the powder is liable to rapid deterioration during keeping, so that when used its carbon dioxide value is very low. In the case of bitartrate powders, Mr. Crampton found on an average 14.04 per cent. of filling, 24.57 per cent. being the highest, 5.32 per cent. the lowest quantity; the latter evidently not being sufficient to prevent deterioration. Powders made up with free tartaric acid contained much more filling, namely, 40.05 and 45.63 per cent., possibly on account of the hygroscopic nature of the free acid. 26.41 per cent. was found in a phosphate powder, another contained no filling, evidently to its detriment. The alum and alum and phosphate powders contained large percentages of filling, 40.76 per cent. being the average, 52.29 per cent. the maximum, 31.54 per cent. the minimum.

Probably this high percentage is necessary to prevent deterioration, especially if but a small proportion of the water of crystallisation has been driven off from the alum. Professor Prescott has given it as his opinion that anything over 20 per cent. of filling should be looked upon as dilution.

Mr. Crampton finally has attempted to make up a domestic baking powder of fair keeping quality, and gives the following formula as answering the purpose well:—

	Oz.
Cream of tartar.....	8
Baking soda.....	4
Corn starch.....	4
	Per Cent.
Total carbon dioxide.....	12.63
Available carbon dioxide.....	10.91

The author's views as to the lines on which legislative regulation of the sale of baking powders should proceed have been given at the commencement of this abstract.

## (B.)—SANITARY CHEMISTRY.

### PATENT.

*Improvements in the Means of and Apparatus for Treating Refuse.* W. Warner, Nottingham. Eng. Pat. 18,719, December 21, 1888. 8d.

THESE improvements have reference to the apparatus commonly known as "Destructors." At the back of the grate is situated a drying hearth on to which the refuse is delivered from a hopper above, placed at the rear end of a reverberatory arch which covers both grate and drying hearth. The construction of the apparatus is such that the main flue for taking off the products of combustion is caused to pass under the drying hearth, which thus receives heat both from above and below. The fire and ash-pit doors are made air-tight so that a forced draught can be used if desired. When employed it is delivered partly below the fire-bars and partly above. The latter current enters the furnace through perforated metal plates so

arranged as to protect the brickwork on each side of the grate, and having air-channels situated behind them. The improvements also have reference to the form of hopper used, the nature of the damper arrangements, and to contrivances for intercepting dust in the flue and facilitating its removal.—A. R. D.

## XIX.—PAPER, PASTEBOARD, Etc.

*Study of the Quality of Paper.* Bull. Soc. d'Encour. pour l'Ind. Nat. 1889, 430—444.

THE increase in the production of paper has led to the introduction of a variety of raw materials in addition to rags, such as hemp, straw, wood-pulp, &c. Of these hemp alone can be considered as an improvement. Attention has been more and more directed to the qualities of paper, its surface, its colour, and at the same time its selling qualities, the result of which is the production of paper of inferior quality, of little strength, and oftentimes destined to a short life. These circumstances have led to the establishment in Germany of a specially appointed laboratory at the Imperial Technical Institute of Charlottenburg, under the direction of Dr. Martens, where papers are systematically examined. The principal points examined are strength, elasticity, nature of sizing, material, thickness, &c.

To determine (1) *the strength*, a number of strips of the paper taken in different directions are tested in a specially constructed machine known as the Gatty-Reisch machine, and the mean taken. The results are expressed in terms of the length of the paper itself necessary to produce the rupture. This is easily obtained by calculation when the weight of the paper and its breaking strain in grammes are known. The same machine indicates automatically the elasticity or extensibility of the paper.

(2.) *Resistance to Rubbing*.—A sample is taken and rubbed between the hands. With a weak paper minute holes soon make their appearance, the number of rubbings determining the quality.

Papers are classed as follows:—

1. Extremely weak.
2. Somewhat less weak.
3. Less weak.
4. Medium.
5. Moderately strong.
6. Strong.
7. Very strong.
8. Extremely strong.

(3.) *Thickness*.—This is measured by means of a micrometer.

(4.) *Ash*.—Cellulose contains less mineral matter than 1 per cent. Any increase in the amount of ash indicates the addition of mineral matter.

(5.) *Microscopical Examination*.—The sample is moistened with a solution of iodine, and the following colourations are obtained:—1. Fibres coloured yellow, in the case of wood pulp. 2. Fibres of cinnamon colour, hemp, linen, cotton. 3. Fibres, uncoloured, pure cellulose. To prepare the paper for microscopic examination the specimen moistened with iodine solution is placed in a porcelain crucible with a little water, a little soda solution added, and the whole boiled. The liquor is coloured yellow if the paper was sized; after a quarter of an hour's boiling, the residue is washed with water. The pulp is then triturated in a mortar with a little water and a portion placed afterwards on the object glass of the microscope. It is easy under the microscope to distinguish to which of the three groups named the specimen belongs.

(6.) *Examination for Chlorine and Free Acids*.—These bodies are very rarely found in papers. The former is recognised by its action on potassium iodide and starch,

The detection of the latter is a matter of great difficulty. Gertzberg recommends treatment with a solution of Congo-red.

(7.) *Determination of Sizing Material.*—Gelatin is detected by the formation of a cloudiness or precipitate when a solution of tannic acid is added to an infusion of the sample of paper in boiling water. Vegetable size is examined for by warming the paper with alcohol and pouring the solution into water; a precipitate is formed if rosin size be present.

To determine the degree of sizing lines are drawn on the paper with a solution of ferric chloride and the other surface is floated in a solution of tannic acid. Ink is formed with less or greater rapidity, according as the paper is well sized or otherwise.

The percentage of water in a paper is also usually determined.

The following are some of the methods of classification adopted at Charlottenburg:—

#### CLASSIFICATION ACCORDING TO STRENGTH.

Classes.	1.	2.	3.	4.	5.	6.
a. Mean breaking length in metres.....	6,000	5,000	4,000	3,000	2,000	1,000
b. Mean elasticity percentage extension .....	1.5	4.0	3.0	2.5	2.0	1.5
c. Resistance to rubbing..	6	6	5	4	3	1

#### CLASSIFICATION ACCORDING TO COMPOSITION.

1st Class.—Paper composed entirely of cellulose, giving a maximum of 2 per cent. of ash.

2nd Class.—Paper composed of cellulose, straw, but without wood pulp, giving 5 per cent. of ash.

3rd Class.—Paper composed of various substances, but without wood pulp, giving less than 15 per cent. of ash.

4th Class.—Paper composed of various substances, whatever the percentage of ash.

Though many objections have been raised to the above classifications, their value has been shown by the fact that of late years the average quality of paper manufactured in Germany has risen and the intervention of the Government has had a good effect on the industry.

The report concludes with the following notes on the microscopic examination of paper:—

The fibres of plants do not present the same appearance in paper as in the natural state, as the processes which they have undergone, to some extent modify them.

*Straw.*—The various kinds of straw usually employed are oat, wheat, barley, rye, maize, and, in China, rice. The fibres present but few distinguishing features; they, moreover, resemble those of hemp and linen. On the other hand, it is easy to recognise in a paper the epidermic cells of straw, and even to determine their source. Fig. 1 represents

Fig. 1.

Fig. 2.

Fig. 3.

a cell from rye straw, magnified 250 times; Fig. 2 that from rice, and Fig. 3 that from maize. The latter has been subjected to the action of chromic acid. The following table gives the dimensions of the various kinds of cells:—

	Dimensions of Cells (in Millimetres).	
	Length.	Breadth.
Barley.....	*103—*214	*012—*014
Rye .....	*086—*315	*010—*016
Wheat.....	*152—*449	*018—*024
Oats.....	*187—*443	*012—*017
Maize .....	*108—*252	*033—*030

These epidermal cells are always accompanied by vascular cells in the form of spirals and isolated rings (Figs. 4 and 5.)

Fig. 4.

Fig. 6.

Fig. 7.

Fig. 5.

Fig. 8.

Fig. 9.

**Wood Fibre.**—There are two kinds of wood fibres usually met with in paper, one from the various kinds of pine, showing very characteristic round pitted vessels (Figs. 6 and 7), the other derived from birch and poplar, having equally characteristic, but totally different, markings.

**Fibres of Dicotyledonous Plants.**—Of these the most important are flax and hemp, and they are very difficult to distinguish from each other. Weisner has lately endeavoured to distinguish them by means of the action of ammonia-copper solution. This solution causes the fibres to swell, and ultimately dissolves away all but the interior canal. The different appearances presented are shown in Fig. 8 (flax) and Fig. 9 (hemp).

This reaction cannot be applied to the fibres in paper, as the mechanical treatment they undergo entirely masks their characteristic features.

The action of the beating rod causes the fibres to split up until they present somewhat of the appearance of Fig. 10 or Fig. 11, if it has not been carried on to the same extent. Occasionally transverse markings make their appearance (Fig. 12); these markings never occur in the case of fibres from monocotyledonous plant.

**Cotton.**—The general microscopical appearance of the cotton fibre is shown in Fig. 13. The spiral appearance,

Fig. 10.

Fig. 12.

Fig. 11.

however, is sometimes simulated by the flax fibre (Fig. 14), and on the other hand occasionally cotton fibre is met with

Fig. 13.

Fig. 14.

Fig. 15.

Fig. 16.

in which it is absent. The ammonia copper reagent causes the cotton fibre to assume the appearance of Fig. 15, the

interior canal having the appearance of a flat ribband. The action of the roll sometimes causes cotton fibre to assume the appearance of Fig. 16.—E. J. B.

*Manufacture of Paper in Japan.* M. Martens. *Bull. Soc. d'Encour. pour l'Ind. Nat.* 1889, 495—498.

THE German Consul at Gioko-Osaka lately sent over a collection of samples of papers made in Japan, which have been examined at the Institute at Charlottenburg according to the methods in use there. The results are given in the following table:—

Name.	Composition.	Ash.	Weight of Square Metre.	Breaking Length.	Extensibility.
		Per Cent.	Grms.	Kilometres.	Per Cent.
Gampi.....	Gampi.....	1.2	12.6	7.2	2.9
Kodsu.....	Kodsu.....	2.3	22.1	4.25	3.9
Mitsumata .....	Mitsumata .....	1.4	18.4	4.08	2.8
Kopigampi .....	Gampi.....	2.4	8.2	7.05	2.1
Ussuyossi.....	( $\frac{2}{3}$ Gampi..... ) ( $\frac{1}{3}$ Mitsumata..... )	1.5	10.0	7.12	2.2
Y'su nedzumi .....	0.8 Gampi .....	4.3	23.1	7.78	3.2
Programi .....	0.2 Silk.....				
Hiro Suki.....	Kodsu .....	1.9	7.8	8.18	2.6
Murasaki.....					
Srogami .....					
Atsu Hinkirigami .....	Gampi.....	1.8	37.8	10.8	3.3
Usu Hinkirigami .....	Gampi.....	1.8	23.9	10.7	3.1
Tu Hyoshi .....	Gampi.....	2.2	84.9	10.5	4.3

By "breaking length" is meant the length of a band of paper suspended vertically, the lower end being free, which the fixed end will support before breaking.

It is remarkable that with European papers the breaking length varies from one to six kilometres, whereas with the Japanese papers it rises to as high as 10.8 kilometres.

The principal materials used for making paper in Japan are: 1. *Wickstomia canescens*; 2. *Edgeworthia pagrifera*; 3. *Broussonetia pagrifera*. Their common names in Japan are Gampi, Mitsumata and Kodsu. Efforts have been made to acclimatise these plants in Europe, but without success. Nearly all the paper is made in Japan by hand labour, the

methods being handed down in families. The methods are very simple. The bark is removed from the tree and allowed to soak for some days to loosen the outer coating. This is removed and the pure bast fibre is allowed to bleach in the sun. It is then boiled in lime water or in a lye made from the ashes of the plants themselves, well washed in water and then beaten into pulp with sticks. The frame on which the paper is made is of thin strips of bamboo and silk.

The paper is sized with boiled rice or some similar starchy material.—E. J. B.

## PATENTS.

*Improvements in Treating or Cleansing Paper-making Materials and other Fibrous Materials and Fabrics.*  
R. Hamilton, Edinburgh, and I. C. Hamilton, Linlithgow.  
Eng. Pat. 1433, January 26, 1889. 11d.

The inventors assist the action of caustic soda in the preparation of paper pulp from rags, esparto, &c., by the addition of the soda or potash salts of certain sulphonic acids obtained by treating olefines with sulphuric acid.—E. J. B.

*Improvements in the Manufacture and Bleaching of Wood and other Pulps and in Apparatus for that Purpose.*  
C. Ramsey, Leeds. Eng. Pat. 1834, February 1, 1889. 8d.

The inventor boils wood chips with lime water in a vomiting boiler. When sufficiently acted upon he treats with a solution of hypochlorite of magnesia at 3° B. for eight hours, the circulation of the liquid being maintained by means of steam. The pulp so obtained is then bleached in a separate vessel with another solution of hypochlorite of magnesia. The solutions are prepared by adding solution of sulphate of magnesia to one of bleaching powder.—E. J. B.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*On the So-called Double Cyanide of Zinc and Mercury.*  
W. R. Dunstan. Pharm. J. February 15, 1890, 653.

SIR JOSEPH LISTER has recently drawn attention to the valuable antiseptic properties possessed by a material which is described in many chemical treatises as a double cyanide of zinc and mercury prepared by precipitating a solution of the cyanide of mercury and potassium with a solution of zinc sulphate (Lancet, November 9, 1889, and January 4, 1890).

During the manufacture of this substance several facts were observed which seemed to throw doubt on the statement that it is constituted of a chemical compound of the two cyanides.

It is stated on the authority of Rammelsberg, in Gmelin's "Handbook," that when the soluble double cyanide of mercury and potassium,  $\text{HgK}_2(\text{CN})_4$ , is decomposed with a solution of zinc sulphate, or when the soluble double cyanide of zinc and potassium,  $\text{ZnK}_2(\text{CN})_4$ , is decomposed with a solution of mercuric chloride, an insoluble double cyanide of mercury and zinc is precipitated, the composition of which is probably represented by the formula—

the chemical changes being expressed by the equations—

It is this substance, freed from soluble salts by washing with cold water, that has been prepared for Sir Joseph Lister. It was observed that in washing the precipitate with cold water large quantities of mercuric cyanide are dissolved from it, only a relatively small proportion, varying from one-fourth to one-fifth of the calculated quantity, remaining in the precipitate. In the absence of knowledge as to the cause of this action, and as to the nature of the precipitate, the manufacture of the substance becomes an entirely empirical operation.

The methods which suggested themselves were—

1. The precipitation of a solution of mercury potassium cyanide with a solution of zinc sulphate—

2. The decomposition of a solution of zinc potassium cyanide with a solution of mercuric chloride—

3. The decomposition of a solution containing a formula-weight of mercury potassium cyanide and a formula-weight of zinc potassium cyanide with just sufficient dilute sulphuric or acetic acid to convert the whole of the potassium present into potassium salt; the cyanides of zinc and mercury would thus be precipitated together:—

4. The simultaneous dissolution of equivalent quantities of freshly precipitated mercuric oxide and freshly precipitated zinc carbonate in strong aqueous hydrocyanic acid—

Having prepared the pure reagents the four above-mentioned processes were successfully put into operation for the purpose of ascertaining whether mercuric cyanide will unite with zinc cyanide in any proportion.

*Method 1.*—This method is substantially the same as that by which the substance used by Sir Joseph Lister has been prepared. Sir Joseph Lister informed the author that the process adopted has been as follows: Cyanide of mercury, 24 oz.; cyanide of potassium (about 95 per cent.), 12 oz. 171 grains; zinc sulphate, 27 oz. 159 grains. The potassium cyanide and the mercuric cyanide are dissolved in 4 pints of cold water, and the liquid is precipitated by the addition of the zinc sulphate dissolved in 12 pints of cold water. These quantities are calculated from the equation given above. The precipitate is collected and washed with two successive quarts of water (see also "Lancet," January 4, 1890).

The substance prepared in this manner is a nearly white powder. The composition of a specimen furnished by Sir Joseph Lister was ascertained by analysis. By washing with cold water, until nothing further is removed, the amount of soluble mercuric salt is determined. The mercury, zinc, and cyanogen were determined by known reliable methods.

The results of the analysis were—

	Per Cent.
Total mercuric cyanide .....	17.77
Mercuric salt removed by cold water ..	2.86
Zinc cyanide .....	67.85

There were also present about 10 per cent. of zinc hydrate, or more probably hydroxy-cyanide, originating partly from the alkali contained in the potassium cyanide, and partly, no doubt, from the decomposition of zinc cyanide.

The supposed double cyanide of zinc and mercury,  $\text{ZnHg}(\text{CN})_4$ , would contain 68.6 per cent. of mercuric cyanide; the substance analysed contained less than one-fourth of this quantity, the remainder having been dissolved by the water present during precipitation and by that used in washing the precipitate.

The substance was now prepared by the same method, but more water was added to the solutions before precipitation. The precipitate was washed until quite free from soluble mercuric salt and dried over caustic soda in a vacuum desiccator, to avoid any possible decomposition by heat. The results of the analysis of this specimen were—

	Per Cent.
Total mercuric cyanide .....	6.77
Mercuric salt removed by cold water ..	None.
Zinc cyanide, including hydroxy-salt ..	33.3

The quantity of water present during precipitation is thus shown to exercise an important influence on the composition of the precipitate. A large quantity of water leads to the retention of much less mercuric salt in a form in which it is not dissolved by water. The amount of mercuric cyanide in this specimen is only about one-tenth of that contained in the compound  $\text{HgZn}(\text{CN})_4$ .

*Method 2.*—Seven grms. of the double cyanide of zinc and potassium were dissolved in water and precipitated by the addition of a solution containing 7.7 grms. of mercuric chloride. The entire quantity of water present was rather less than in the preceding experiment. The precipitate

was washed with cold water until free from soluble mercuric salt, dried over caustic soda and analysed. The following results were obtained :—

	Per Cent.
Total mercuric cyanide .....	9.67
Mercuric salt removed by cold water .....	None.
Zinc cyanide .....	80.61
Zinc hydroxy-compound (calculated as hydroxide) .....	7.3

This substance contains about one-seventh of the quantity of mercuric cyanide, represented by the formula  $\text{ZnHg}(\text{CN})_4$ .

**Method 3.**—Equivalent quantities of the mercury potassium cyanide and the zinc potassium cyanide were dissolved in water, and just sufficient diluted sulphuric acid was added to remove the whole of the potassium. The precipitate was collected, washed until free from soluble mercuric salt, and dried over caustic soda. The following are the results of its analysis :—

	Per Cent.
Total mercuric cyanide .....	8.46
Mercuric salt removed by cold water .....	None.
Zinc cyanide .....	81.9
Zinc hydroxy-compound (calculated as hydroxide) .....	6.9

This method also failed to produce the compound  $\text{ZnHg}(\text{CN})_4$ ; the amount of mercuric cyanide contained in it is only about one-eighth of that represented by this formula.

**Method 4.**—Equivalent proportions of freshly precipitated mercuric oxide and zinc carbonate were thoroughly incorporated and added to a small quantity of concentrated aqueous hydrocyanic acid. Reaction was immediate, carbon dioxide being copiously evolved. The mixture soon lost the odour of hydrocyanic acid. More was then added, until the odour remained permanent after some hours, the mixture being frequently stirred during this time. The precipitate was filtered, washed with cold water until no mercuric salt could be detected in the washings, and dried. It yielded on analysis the following results :—

	Per Cent.
Total mercuric cyanide .....	1.6
Mercuric salt removed by cold water .....	None.
Zinc cyanide, including a little hydroxy-compound .....	98.4

This method is no more successful than those previously tried, in producing a double salt of the formula  $\text{ZnHg}(\text{CN})_4$ . It seemed, however, to be a method which might possibly be useful in the preparation of the antiseptic material, since the product is remarkably pure. In the experiment described above, a saturated aqueous solution of hydrocyanic acid was employed, and it was thought that the large quantity of water present had prevented the retention of much mercuric cyanide in an insoluble form. Equivalent quantities of mercuric oxide and zinc carbonate were therefore suspended in a little alcohol, and the vapour of hydrocyanic acid passed into the liquid until reaction was complete. On filtering and thoroughly washing the precipitate it was found that even under these favourable conditions nearly the whole of the mercuric cyanide had been dissolved.

The analyses which are recorded above of the precipitates obtained by four distinct methods, each of which is likely to afford the supposed compound, provided that it is not decomposed by water, conclusively disprove the existence of a double cyanide of the formula  $\text{ZnHg}(\text{CN})_4$ . Gmelin's suggestion that such a compound may be prepared by precipitating a solution of mercury potassium cyanide with a solution of zinc sulphate or a solution of zinc potassium cyanide with mercuric chloride is clearly erroneous.

Although there can no longer be any doubt that the compound  $\text{ZnHg}(\text{CN})_4$  cannot exist, yet there remains to be explained the remarkable fact disclosed by the foregoing results that the precipitated zinc cyanide retains some quantity of mercuric cyanide so firmly that it cannot be removed by washing the substance with cold water. In each of the precipitates produced by the four different processes the mercuric cyanide appears to be contained in two forms. The greater part of the mercuric cyanide is

evidently in the free state, and is therefore easily dissolved by cold water. A smaller part is not removed by cold water, although mercuric cyanide is a soluble salt. How is this smaller amount of mercuric cyanide retained by the zinc cyanide? Is it (1) chemically combined as a double cyanide? or (2) as a compound of mercuric hydroxy-cyanide with zinc cyanide? or (3) as a compound of zinc hydrate (or hydroxy-cyanide)? or (4) is it merely *occluded*\* by particles of zinc cyanide during precipitation, so that in consequence of a protective coating of insoluble zinc cyanide the water is unable to come into contact with the mercuric cyanide? Experimental investigation alone can furnish a conclusive answer to these questions.

The author speculates on the cause of the presence of mercury cyanide not in a state of combination, and gives an account of experiments to determine this point.

#### Report on New Fine Chemicals of Therapeutic Value.

Merek's Bull, 1889, 85—92; also 93—102.

THE MYDRIATIC ALKALOIDS OF THE SOLANACEÆ. — *Hyoscyamine* (this Journal, 1888, 584).

This alkaloid is principally obtained from the leaves and seeds of *Hyoscyamus niger*, though more recently from *Atropa belladonna*. In the trade three modifications are to be found at present:—*Amorphous Hyoscyamine*, not colourless, from *Hyoscyamus niger*; *Crystallised Hyoscyamine* from *Hyoscyamus niger*, chemically pure, perfectly white, and very light, and consisting of the pure alkaloid; and *Commercial Hyoscyamine*, chemically identical with the preceding kind, but obtained from *Atropa belladonna*. The sulphates, hydrochlorides and hydrobromides are also to be met with, but it is the alkaloid which is principally used.

*Amorphous Hyoscyamine* is a light brown, syrupy liquid of alkaline reaction, but little soluble in water though readily so in acidulated water, alcohol, ether and chloroform.

*Crystallised Hyoscyamine* is met with in silky crystals, permanent in the air, melting at  $108.5^\circ \text{C}$ ., and possessing the same solubility as the preceding kind.

*Commercial Hyoscyamine* (*Atropa belladonna*) in its physical and chemical properties is similar to the crystallised variety; its physiological and therapeutical behaviour has not yet been reported on.

Generally speaking, the physiological and therapeutic effects of hyoscyamine are similar to those of atropine, especially as regards mydriatic action. In recent practice its use in ophthalmology has been almost abandoned, and it is now principally employed as a hypnotic in mental disorders, or as an anodyne and anti-spasmodic in asthma, epilepsy, &c. According to *Gauke* the pure crystallised alkaloid is the best form for administration.

*Hyosine*.—This alkaloid was discovered by Ladenburg in the mother-liquors from the manufacture of hyoscyamine. Hyosine has never yet been obtained in the crystalline, or even solid form. It is a syrupy liquid, with difficulty soluble in water, though easily so in alcohol and ether. It yields well crystallised salts, among which the following are at present recognised as possessing therapeutic value:—*Hyosine hydrochloride*, *hydrobromide*, and *hydriodide*.

In consequence of its physical properties the pure alkaloid is not used in medicine.

All the salts of hyosine are soluble in water, and insoluble in strong alcohol and in ether.

In 1881 Hirschberg discovered that hyosine is a very powerful mydriatic, but he added that owing to its ready liability to act on the organ generally, caution must be exercised in its ophthalmologic use. Emmert (Archiv. für Augenheilkunde, 1882, 183) and Walter (Inaugural Dissert. Dorpat, 1887) fully endorsed Hirschberg's conclusion. Emmert recommends hyosine in all cases where energetic and prompt mydriatic action is desired. C. Walter found

\* It has been suggested to the author that some explanation of the use of this word should be given, in view of its special application by the late Professor Graham to designate another, but apparently analogous, class of facts. He therefore takes this opportunity of stating that the word is here used in its strictly etymological sense, being derived from *occludo*, "to shut up" or "lock in."

that a more rapid and greater dilation of the pupil was obtained with a  $\frac{1}{4}$  to a 1 per cent. solution of hyoscyne than with a 1 per cent. solution of atropine, the duration of *mydriasis* (dilation of pupil) however being briefer.

Remarkable hypnotic effects with the hyoscyne salts are reported especially in the case of insane patients, and most especially in extreme cases of excited or raving insanity.

In the tremors of *paralysis agitans*, even in very grave cases, hyoscyne has been found by *Erb* to act as a most excellent palliative. In other nervous disorders it has been successfully used.

*Tertiary Amyl Nitrite* (Bertoni's "amylonitrous ether"),  $C_5H_{11}NO_2$  (see this Journal, 1889, 1003).—The boiling point of this "ether" is not as stated (*loc. cit.*), "about 30° C.," but as Bertoni now states "93° C."

*Antipyrine and Nitrites. Their Antagonism.*—According to Knorr, when an acid aqueous solution of antipyrine is brought into contact with potassium nitrite, a slightly soluble crystalline substance of bluish-green colour is formed, viz., isonitroso-antipyrine,  $C_{11}H_{11}N_3O_3$ .

H. C. Wood and J. Marshall have shown this latter compound to be devoid of any action either on dogs or rabbits; also a dog when given antipyrine followed very soon by ethyl nitrite, showed no abnormal condition whatever. Antipyrine would thus seem to be capable of diminishing and even wholly neutralising the possible detrimental action of a nitrite, whilst, on the other hand, antipyrine itself is debarr'd from all action by the presence of sufficient nitrite.

*Bromoform*,  $CHBr_3$ .—A colourless limpid liquid of a peculiar, sweetish, agreeable taste. It is easily soluble in alcohol, but only slightly so in water, five or six drops dissolving in 100 grms. of water only after long and violent shaking. This aqueous solution, if well corked, may be preserved for a long time.

Bromoform is an anæsthetic like chloroform, but it does not irritate the mucous membrane of the mouth as chloroform does. Moreover, experiments by Horroch (Oesterreich. Med. Jahrb. 1883, 497) have proved that complete anæsthesia is obtained by much smaller respiratory doses of bromoform than of chloroform. By internal and subcutaneous treatment with bromoform, warm-blooded animals were placed in *narcoses* lasting from four to eight hours. These were induced within 5 to 36 minutes after subcutaneous administration of 0.1—1.0 grm. of bromoform, and were always accompanied by a fall of temperature of from 3° to 5° C.

Great success attended the use of a solution of bromoform in water to which a little alcohol had been added, in cases of whooping cough complicated with pneumonia, by Stepp and Goldschmidt (*Deutsch Med. Wochenschr.* 1889, No. 31).

*Bryonia alba* and its active constituent, *Bryonidin*, have recently been found to act as a most powerful *Hæmostatic* (capable of arresting hæmorrhage).

Petresen and Eliau (*Deutsch. Med. Zeit.* 1889, 487) commend the merits of white bryony (*Bryonia alba*) as a hæmostatic of prime efficacy. This is a new use of the drug. An infusion is made of 20—25 grms. of the dry root in 300 grms. of hot water, and the liquid is evaporated down to 150 grms. This liquid is mixed with syrup for administration. The above investigators succeeded in isolating from bryony root, besides several resins and acids, also a glucoside which they considered to be *Bryonin*. Its general action corresponds to that of the root. However, more recently still, A. Maukowsky (Inaug. Dissert. Dorpat, 1889) reports that he has found two glucosides in *Bryonia alba*, viz., bryonin and bryonidin, and he further states that only bryonidin possesses toxic, and therefore therapeutic properties. It is to be specially noted that red bryony (*Bryonia dioica*), easily confounded with the preceding, possesses no hæmostatic virtues whatever. The physiological action of *Bryonia alba* consists of a progressive contraction of the capillaries, which may be continued until a complete arrest of the circulation is secured. For antihæmorrhagic effect *Bryonia alba* appears to far transcend any other agent as yet known.

*Chloral-amide*,  $CCl_3.CH(OH)(NH.CHO)$ , a recently discovered and synthetically prepared hypnotic formed by the addition of anhydrous chloral ( $CCl_3.CHO$ ) to formamide ( $CHO.NH_2$ ). Chloral-amide is prepared in colourless crystals, soluble in 9 parts of water, or in  $1\frac{1}{2}$  parts of 96 per cent. alcohol. Its taste is mildly bitter, and not acrid. Its aqueous solution must be prepared cold, since the compound decomposes when heated above 60° C. Its aqueous and alcoholic solutions are not affected either by weak acids or silver nitrate solution. By caustic alkalis they are decomposed rapidly, and slowly by alkaline carbonates. Therapeutic value has been tested by Hagen and Hübner, Lettow, Rabow, Reichmann, and Kny (*Wiener Med. Presse*, 1889, 1361). As a hypnotic it has been proved superior to chloral hydrate. Of most value in cases of nervous insomnia and similar disorders. Disagreeable accessories not noticed (Rabow). This hypnotic may be taken internally as a powder, prepared by triturating 1—3 grms. of the amide with 1 grm. of fennel-oil sugar (*Eulosaccharum Feniculi*).

*Mercury Preparations.*—Their relative toxic strengths compared. As the result of a series of experiments by Zeising of Breslau (First Congress Germ. Dermatolog. Soc. Prague, June 1889) it was shown that the absolute mercury strength of any preparation used has less share in the toxic result produced than the degree of absorbability of the preparation into the organism.

*Dithiosalicylate of Sodium*—

*Dithiosalicylate of Sodium I. and II.* prepared by Baum are two isomeric substances constituted as above. The salt No. II. has been experimented upon by Lindenhorn, who found it to be a valuable antiseptic and disinfectant, much more powerful than salicylate of sodium.

It is a greyish-white powder, very hygroscopic, and soluble in water. Any acid added to the solution produces a precipitate of yellow viscid drops, consisting of dithiosalicyllic acid. Ferric chloride added to the aqueous solution of the soda salt produces a faint violet colouration. According to Hueppe a 20 per cent. solution of dithiosalicylate of sodium destroys the spores of *anthrax* in the course of 45 minutes. Salicylate of sodium has no such action. Lindenhorn claims the following advantages over ordinary sodium salicylate: The dithiosalicylate need not be given in such large doses as salicylate. It has no ill effect on the stomach, heart, or large vessels; does not produce collapse nor singing in the ears. It promises to be a more valuable anti-rheumatic.

*Improvements in the Production of Oxygen and Hydrogen in Large Quantities by Means of the Electrolysis of Water, applicable for Ballooning and other Uses.* D. Latchinoff, St. Petersburg, Russia. Eng. Pat. 15,935, November 3, 1888. 11d.

See under X1., page 196.

*A Process for making Hydrogen Peroxide.* Dr. Traube, Breslau, Germany. Ger. Pat. 48,542, December 5, 1888.

SCHÖNBEIN has shown (*Verhand. d. Naturforsch. Ges. in Basel*, N.F., Part II., 426) that when zinc amalgam is shaken up with water and air, there is formed, together with zinc hydrate, a small quantity of hydrogen peroxide, which even after long shaking does not rise above  $\frac{1}{33000}$  part. According to Traube the reactions are as follows:—

I.

II.

Hydrogen peroxide therefore is found in such a small proportion only because it is again almost completely decomposed by the zinc. This does not, however, occur if an alkaline earth is present. In such a case the hydrogen peroxide forms a superoxide of the alkaline earth. Accordingly zinc amalgam and milk of lime are shaken up with air when a precipitate of zinc hydrate and calcium superoxide separates, which is decomposed by an acid that forms an insoluble compound with zinc and lime. Lime water does not give such good results as milk of lime. Cadmium amalgam acts in the same way as zinc amalgam. The amalgam should contain at the most 1 part of zinc or cadmium to 1,000 of mercury.—H. S. P.

*An Improved Process for Producing Ozone Water in which the Ozone is Retained for a Considerable Period without Alteration.* B. Graf and F. Pickenbrock, Berlin, Germany. Eng. Pat. 15,526, October 3, 1889. 4d.

A SMALL quantity of hydrochloric acid and of an alkaline chloride is added to the water, through which ozonised oxygen is passed, to improve the keeping properties of the product. (Compare this Journal 1890, 3—10.)—G. H. B.

## XXII.—EXPLOSIVES, MATCHES, Etc.

*Determination of the Detonating Point of Explosives.* Bein. Zeits. f. angew. Chem. 1889, 667—669.

THE author has been in the habit of using Horsley's method, which consists of floating on an oil-bath a small dish containing the powder and heating until the powder fires, noting the temperature of the bath at the time. To avoid sublimation of sulphur to a certain extent, he did not introduce the powder until after the bath had been heated. The method has disadvantages as for higher temperatures (200° to 450°); special baths must be used; and, again, the thermometer does not necessarily give the true temperature of the powder. An apparatus is described which would seem not to possess these disadvantages. A test tube is fixed in the axis of a sheet-iron cylindrical vessel with conical top. This sheet-iron vessel is about 30 cm. in height and 8 cm. in diameter; it is surrounded by another similar sheet-iron vessel covered with asbestos, and about 15 cm. in diameter. The bottom of the outer vessel contains a hole, which admits of the entrance of a Bunsen flame. The whole forms a sort of air-bath. When the temperature has been raised trials are made by dropping a few grains of the powder under examination into the test tube. The result is watched through spy holes in the side of the apparatus, and the temperature is registered by a thermometer in the tube. The apparatus seems to give very good results, and as many as 20 or 30 determinations may be made in an hour.—T. L. B.

*Report upon Questions relating to the Employment of Explosives in Presence of Firedamp.* Annales des Mines, 14, 1888, 197—376; and Proc. Inst. Civil Eng. 99, 100.

THIS is an exhaustive report of a special sub-commission appointed by the French Government to determine the behaviour of the different explosives capable of use in mines in the presence of firedamp. The sub-commission was composed of 11 members, of whom Mr. Mallard was president. The report is divided into five chapters, preceded by an historical note, and followed by tables and appended notes. Chapter I. describes the apparatus and mode of experiment. Chapter II., explosives freely suspended in firedamp mixtures. Chapter III., explosives exploded in a closed vessel. Chapter IV., mode of firing shot in the mine; and, Chapter V., conclusions.

The conclusions are as follow:—

1. Even explosives under water can inflame firedamp mixtures with air by means of the dust of the mine.

2. The greater number of known explosives are capable of igniting firedamp mixtures when exploded freely in the atmosphere. Among these explosives are dynamite, gun-cotton (either military or mining, particularly the latter), dynamite gelatin, and Paulille's ammoniac dynamite.

3. It is, however, possible to find explosives which detonate at a temperature sufficiently low to avoid inflammation of firedamp mixtures, at least in the great majority of cases, when freely exploded in the atmosphere. Among the explosives experimented on which approximately fulfil this condition are: (1), the intimate mixture of 50 parts dynamite with 50 parts of crystallised carbonate of soda, or sulphate of soda with 10 equivalents water of crystallisation, ammonia alum, and ammonium chloride; (2), Monlin-Blanc pyroselin powder; (3), mixture of 20 parts dynamite, at 75 per 100, and 80 parts of nitrate of ammonia; (4), mixture of 20 parts of gun-cotton titrating 173 cc. nitrogen dioxide and 80 parts nitrate ammonia; (5), bellite, of which the composition is not known with certainty, and the experiments have not been sufficiently numerous; (6), Favier's explosive, containing 90 parts of nitrate of ammonia, 10 parts mononitronaphthalene, which appears to equal bellite in security. It requires, however, further experiment.

4. Because of the complexity and variability of the phenomena occurring during the detonation of explosives free to air, it will be prudent to avoid firing shots in the mine, even with charges considered the safest, at points where the mixture of air and firedamp is inflammable. The choice of explosives must be considered as diminishing danger, but not as absolutely suppressing it.

5. It is necessary to employ the explosives under conditions such as to develop from them the maximum useful work. Economy and security are in accordance to recommend this rule. To accomplish this the following conditions are necessary. The explosive must be rammed with care, and the hole must be sufficiently deep. No void space must be left either in front, behind, or round the cartridge. The Bickford fuse must not be placed in contact with the explosive if it is used, and the dangers of the fuse are sufficiently great to make it desirable to replace it by some more certain mode of ignition.

The commissioners further remark that their conclusions led to abandoning the use of mining-powder in mines where firedamp is known to exist, and even to place under suspicion ordinary dynamite, dynamite gum, ammoniac dynamite, such as is actually manufactured. Of these, dynamite gum appears to be the most dangerous. The explosives which give greatest security are the binary mixtures of dynamite, gun-cotton, dinitrobenzene with nitrate of ammonia; but the best mode of manufacturing and protecting these mixtures from atmospheric moisture has still to be experimented on. The breaking up of the coal and rock by them also requires practical study. The commission recommend the Government to prepare sample cartridges and issue them to mining engineers who may be willing to conduct practical trials with them in ordinary work.

To the main report is added a supplementary one dealing more minutely with the conditions of the explosion of firedamp, and in the conclusions it is stated that the temperature of inflammation of firedamp is 500° C., but it is necessary that the action of this temperature should be prolonged to produce ignition. Because of this fact, and the almost instantaneous mixture of the products of combustion with the atmospheric air which causes them to cool rapidly, explosives in which the temperature of explosion is less than 2,200° C. are incapable of inflaming firedamp mixtures when detonated under normal conditions.

The hole, however, must be carefully tamped, as the greater the imperfection of wadding, the greater the danger, and free explosion in air is the most dangerous of all. In the supplementary report the experiments with binary mixtures are detailed minutely, and it is again stated that nitrate of ammonia is the best substance to be used in connexion with the explosives. The reports are illustrated with figures of the apparatus used, and numerous tables are given.

## PATENTS.

*Improved Machine for Making Cartridges of High Explosives.* W. D. Borland, London. Eng. Pat. 1321, January 24, 1889. 8d.

THE invention consists essentially of a contrivance for causing an intermittent feed of the explosive material into the cartridge case or tube or other suitable mould in which the explosive has to be formed, and also causing the plunger which presses the material to work on and not in the material, and to act with a certain maximum force which can be determined beforehand. For details of the machine, the specification, which is furnished with drawings, must be consulted.—W. M.

*A Process for Granulating and Glazing Gelatinous Explosives.* O. Imray, London. From F. C. Glaser, Berlin, Germany. Eng. Pat. 2078, February 5, 1889. 4d.

THE compound, while still in a plastic condition, is moulded into sheets or rods, which are cut into small pieces, dried, and subdivided by passing them between grooved rollers. The dust is sifted out for subsequent compounding and the granules are polished in an inclined revolving vessel and glazed with plumbago.—W. M.

## XXIII.—ANALYTICAL CHEMISTRY.

*Electricity in Chemical Manipulation.* R. Fessenden. Chem. News, 61, 4—5.

DESCRIPTION of chemical apparatus in which electricity is employed.

1. *For Rapid Evaporations in Vacuum.*—A is a piece of plate glass, with hole bored in centre, and fitted with a cork, H, carrying two wires which are connected to the ends

Fig. 1.

of the platinum coil W, packed in magnesia. The dish, with the liquid, is placed on stand B, and covered by bell-jar. F is connected to a filter pump, and the ends of the coil to a primary battery. More liquid is added from time to time through E.

2. *Automatic Heat Regulator.*—A is a piece of glass tubing, connected, first, to vertical piece of thermometer

tubing B, second, to reservoir C, having stop-cock at D, and, third, to the T-piece E.

K is connected to the bulb of an air thermometer. The branch H is connected by india-rubber tubing to the vessel, I, containing mercury, which may be raised or lowered by means of the pulley. Through C a carbon rod resting on

Fig. 2.

the capillary portion of C; through A, a platinum wire, X is fused. O is an electro-magnet, and the connexions are as shown. Q is a plunger, held by a spring in a piston, so that when the magnet is not acting, the gas can pass freely through R to R<sub>2</sub>. The apparatus is used as follows: the cocks H and T being open, whilst G and D are shut—it is then a simple air thermometer. When used as a regulator, cocks G and D are opened, and the height of mercury adjusted so that it nearly touches the carbon rod M; cocks G, H, and T are now closed; if the temperature rises the electric circuit will be complete, and the plunger will diminish the gas supply. This apparatus will maintain the temperature constant to 0.5°, it may be used with any pressure of gas, and with one galvanic cell, will work for months.

—W. W. H. G.

*New Apparatus for Testing Materials in Tension and Compression.* H. Bonnami. Le Génie Civil, 15, 1889, 475; and Proc. Inst. Civil Eng. 99, 7.

MR. BUGNET, of Havre, has succeeded in producing a simple, accurate and automatic machine, suitable for testing Portland cement, in a very ingenious manner.

His apparatus consists essentially of two vertical tubes, the one being rigid and the other flexible; the latter terminating in a reservoir provided with an escape valve. Both tubes are connected to a pan, closed above by an india-rubber diaphragm. The tubes and pan are filled up to a datum line with some suitable liquid, preferably mercury; the space between the mercury and the diaphragm is filled with water.

On raising the reservoir no pressure is exerted on the diaphragm if the escape-valve be closed; care being taken that the height of the reservoir above the datum never exceeds 760 millimetres (29.92 in.). On opening the valve the mercury slowly escapes, and exerts a pressure on the diaphragm in virtue of its height in the rigid tube, to which it is proportional.

The whole of the apparatus is mounted on a cast-iron stand. The pan, which is a part of the same casting, has two cavities; one is in communication with the rigid tube, and the other with the flexible tube and reservoir. The upper part of the flexible diaphragm is covered by a brass disc, on which a bent standard is pivoted; one of the pulling slips is suspended from the upper part of this standard, and the other clip is provided with an adjusting screw for bringing the clips up to their work when the briquette is inserted.

The load on the briquette is measured by the height of the mercury column in the rigid tube. The height

being indicated and registered by means of a float, a string attached to it passes over a ratchet-pulley, and is kept tight by a balance weight on the other end. The ratchet allows the index to rise, but not to fall, unless the pawl is released. The reservoir valve is provided with a divided disc to indicate the amount of opening, and consequently the rate at which the load is applied to the briquette. The reservoir itself slides up and down a guide pillar; on reaching the top it is held in position by a catch. The *modus operandi* is as follows: The briquette having been inserted in the clips and screwed up, the reservoir is raised and the valve opened, when the mercury gradually rises in the fixed tube, and applies the load on the specimen until fracture occurs. The mercury suddenly falls, but leaves the index in its highest position, thus indicating the breaking stress in kilogrammes per square centimetre on the fractured area.

By a slight modification the apparatus may be adapted for compression as well as tension tests.

*The Determination of the Specific Gravity of Viscous and Frothy Syrups, &c.* A. Genieser. *Zeits. f. angew. Chem.* 1890, 44—45.

THE removal of the air from frothy syrups in order to determine their specific gravity, is often effected by heating them on the water-bath in a funnel with its tube closed by a glass rod. Even after eight hours' heating at 100°, the complete removal of the air cannot be effected in this way, and further there is a considerable loss of moisture noticeable after half an hour's heating. To overcome these sources of error the following process is adopted:—The syrup is first warmed so as to thin it, filtered through a wire gauze and transferred to a specific gravity bottle, which is about two-thirds filled with it and weighed. The bottle is then heated in a suitable bath (oil-bath or bath of hydrochloric acid) until the syrup boils briskly and is kept for a few minutes at this temperature. The air collects above the liquid in bubbles and these are broken up and the air driven out by the addition of water after the bottle has cooled to 17.5°. The bottle is filled up with water and the whole weighed. The difference between the two weighings will give the weight of water added and thus the weight of syrup (free from water) is got; the weight of water contained by the bottle at 17.5° being known, the specific gravity of the syrup is obtained.

—C. A. K.

*Detection of Small Quantities of Nitrous Acid.* G. Lunge. *Zeits. f. angew. Chem.* 1889, 666—667.

SOLUTION of  $\alpha$ -naphthylamine, even when made from the pure white salt, very soon becomes coloured, and the original delicacy of the reagent is lost. Furthermore, in very dilute solutions (such as one to a thousand millions), the reaction is exceedingly slow, so that in some cases it is even doubtful whether the colouration may not be due to nitrous acid contained in the air. Warming hastens the reaction, but even then 15—20 minutes may be necessary. Høsvay has shown that colouration is more quickly effected if acetic acid be used instead of hydrochloric or sulphuric; and, besides this, the reaction is more marked. He points out also that by boiling solid naphthylamine with water, and pouring off the clear liquid, a solution is obtained which does not darken on standing. He carries out the test as follows:—(a.) 0.5 gram. of sulphanilic acid is dissolved in 150 cc. of dilute acetic acid. (b.) 0.1 gram. of solid naphthylamine is boiled with 20 cc. of water, and the colourless solution poured off; 150 grms. of dilute acetic acid are then added to this solution. About 20 cc. of the sample solution are taken, a few cc. of the sulphanilic acid solution added, and the whole warmed to 70°—80° when naphthylamine solution is added. Red colouration is produced very quickly if only small quantities of nitrous acid be present; if comparatively large quantities be present only a yellow solution is obtained, unless a more concentrated naphthylamine solution is used. The present author introduces an improvement by mixing together the sulphanilic acid and naphthylamine solutions, and keeping them so mixed for use. When the two solutions are kept separate, small quantities of nitrous acid are absorbed from the air by con-

tinual opening of the bottles; such absorption is not indicated by the solutions themselves, and whenever evidence of the presence of nitrous acid in a sample is obtained it is necessary to perform a separate experiment with only the reagents themselves. If the two be kept mixed, however, any absorption of nitrous acid from the air is at once indicated; the solution then only needs treating with a small quantity of zinc dust to fit it perfectly for use.

—T. L. B.

*Analysis of Tungsten, Ferro-Tungsten, Tungsten Steel, Ferro-Chromium, and Chromium Steel.* A. Ziegler. *Dingl. Polyt. J.* 274, 513—528.

TUNGSTEN for steel-making occurs in commerce as a brownish or black powder. Of two samples examined, one was of the former hue, and was partly oxidised, containing only 75 per cent. of tungsten (1.), while the other was a pure black, and in it 91 per cent. of the metal was present (11.). Various methods of attacking these were tried:—Roasting in air (compare *Chem. Zeit.* 13, 65) is slow and uncertain, though it may be aided by the use of ammonium nitrate; hydrofluoric acid only acts on the impurities present, such as iron, manganese, and silicon; aqua regia is effective only on prolonged and repeated digestion; alkaline carbonates act only on the oxide, and therefore require the aid of air to attack the metal; it is possible to approximately gauge the extent of oxidation of any given sample by determining the quantity of alkaline tungstate formed by dusting it into a bath of alkaline carbonate kept very fluid so as to allow the particles to sink promptly; 240 parts of sodium carbonate and 160 parts of nitre are a good flux, but attack platinum; sodium bisulphate dissolves the substance readily; nitric acid is almost without action; hydrochloric acid and potassium chlorate act but slightly. All the above reagents behave alike to the two varieties of commercial tungsten. Strong sulphuric acid formed a certain amount of the blue oxide ( $W_2O_3$ ) with the brownish sample, and had no action on the black; heated, it yielded the blue oxide in both cases; and on cooling gave a blue solution with Sample 11.; concentrated hydrochloric acid caused the evolution of gas with (1.), and the formation of a blue colouration becoming violet; with (11.) a blue solution was obtained, which finally became yellow; on heating, both samples gave a yellow liquid, from which a yellow solid ( $?WO_3$ ) eventually separated; hydrofluosilicic acid of sp. gr. 1.06 gave a permanent blue solution with (1.), and a turbid liquid, blue only by reflected light (on filtering which the liquid was found to be colourless), with (11.). On this a method for determining the proportion of oxide to metal might be based, though strict attention to conditions would be necessary, as, by the use of excess of acid, no perceptible reaction occurred with either specimen. Sodium nitrate was found to attack both samples thoroughly. The separation of tungstic acid from an alkaline tungstate is best effected by sulphuric or nitric acid, and not by hydrochloric acid, which retains a portion in solution.

*Analysis of Commercial Tungsten.*—On these facts the following method is based:—One-half to 1 gram. of the sample is finely powdered in an agate mortar and fused with sodium nitrate in a silver crucible for about half an hour, and the melt dissolved by digestion with water. Any insoluble matter is filtered off and treated with strong hydrochloric acid; should it dissolve slowly or leave a yellow residue, it contains unattacked tungstic acid, and the residue must be re-fused with sodium nitrate, and its aqueous solution dealt with just as the main quantity was. A portion of the tungstic acid present in the residue will have been dissolved by the hydrochloric acid and must be recovered by evaporating twice with nitric acid, the last traces being obtained, if thought necessary, by nearly neutralising the filtrate, acidified with nitric acid, by means of ammonium carbonate, and precipitating with mercurous nitrate. The aqueous solution of the main melt is evaporated to dryness with excess of nitric acid, heated to 120° C., an acid solution of ammonium nitrate added, filtered, and the tungstic acid washed with the same liquid. Traces of tungstic acid are separated by concentrating the filtrate,

nearly neutralising with ammonium carbonate, and precipitating with mercurous nitrate, allowing the mercurous tungstate to settle for 12 hours. At this stage one has (i.) the whole of the tungsten as tungstic acid or mercurous tungstate on the filter; and (ii.) the iron and manganese (together with a little silica) in the filtrate. (A trace of iron which was originally present in the melt as sodium ferrate may be found in the filtrate from the mercurous nitrate treatment; the author suggests the avoidance of this possibility by decomposing the ferrate by passing a stream of carbon dioxide through the aqueous solution of the melt.) The tungsten may be determined by dissolving the mixed tungstic acid and mercurous tungstate through the filter with ammonia, evaporation in a platinum dish, cautious ignition until the weight is constant, and treatment with hydrofluoric acid and re-ignition to volatilise traces of silica, and final weighing. The iron and manganese are best determined in another portion, so as to avoid the difficulty of dealing with the small quantities existing in the filtrates from the mercurous nitrate precipitations of the tungstic acid apart from the main portion dissolved in hydrochloric acid. For this purpose another fusion of the original sample with sodium nitrate is made, the residue insoluble in water dissolved in hydrochloric acid, the solution precipitated with sodium carbonate, the mixed oxides ignited and weighed as  $\text{Fe}_2\text{O}_3$  and  $\text{Mn}_2\text{O}_4$ , then dissolved in hydrochloric acid, evaporated with sulphuric acid (any silica filtered off), in excess of zinc oxide added, the solution made up to a known volume, a portion drawn off and the manganese in it determined by titration with potassium permanganate.

The silica in the sample is best determined on a fresh portion, evaporating the aqueous solution of the melt with sulphuric instead of nitric acid, thus getting the tungstic acid (containing all the silica) in a state less soluble in ammonia than that got by nitric acid, but more readily washed. The weight of the mixed silica and tungstic acid is taken, the former volatilised by hydrofluoric acid, and thus its weight determined.

The author recommends sodium bisulphate, as an alternative flux for attacking tungsten, only when speed is desired at the expense of rigid accuracy, the tungstic acid not separating as perfectly as with sodium nitrate; the mode of work is similar to that described above.

**Analysis of Ferro-Tungsten.**—This may be effected by the process given for commercial tungsten, but the following is a reliable alternative:—1 gm. of the finely powdered sample (obtained by crushing in a diamond mortar and sifting) is gently warmed for some time with concentrated hydrochloric acid, diluted and evaporated with nitric acid of sp. gr. 1.2; the use of dilute aqua regia may be substituted for this treatment. The solution is evaporated on the water-bath with excess of strong nitric acid, and when as nearly dry as possible treated with a solution of ammonium nitrate acid with nitric acid, and filtered. The residue consists of tungstic acid, silica, and unattacked substance. The filtrate contains iron, manganese, and traces of tungsten and silicon; the two latter can be precipitated by mercurous nitrate if it be not intended to determine the two former on the same portion. The residue is dissolved off the filter with hot ammonia solution (1:3) into a platinum dish, evaporated to dryness, ignited, and weighed. Any undissolved matter (original substance not fully attacked) may be fused with sodium nitrate as described under the head of "*Analysis of Commercial Tungsten*."

Silicon is best determined on a fresh portion by heating with sulphuric acid (it is noteworthy that the dilute acid (1:3) acts on ferro-tungsten with evolution of sulphuretted hydrogen), then adding dilute aqua regia to complete the reaction, evaporating until sulphuric acid begins to be driven off, adding water, filtering, and washing with 1 per cent. hydrochloric acid; as silicon, and not tungsten is being estimated, a turbid filtrate is harmless. The precipitate is ignited, weighed, treated with hydrofluoric acid, reweighed, and the silicon reckoned by difference.

**Analysis of Tungsten Steel.**—5 grms. of steel is warmed with 80 cc. of nitric acid of sp. gr. 1.2, 100 cc. of sulphuric acid (1:3) added as soon as the action is over, and

evaporated until sulphuric acid begins to escape. Water is added, the residue is collected, washed with 1 per cent. hydrochloric acid, and used for the determination of silicon and tungsten, separation being effected by hydrofluoric acid. The filtrate serves for the estimation of manganese. Carbon is determined by Eggert's method.

**Analysis of Ferro-Chromium.**—Ferro-chromium, unlike ferro-tungsten, which is almost indistinguishable from ferro-manganese, possesses a characteristic radiating crystalline appearance, and is notably brittle; a sample may be prepared for analysis by crushing in a diamond mortar and sifting the product.

The specimen used by the author contained 67 per cent. of chromium; it was little acted on by nitric or sulphuric acid or aqua regia; hydrochloric acid attacked it fairly, but left a refractory residue. In its tendency to form refractory compounds with iron and manganese, chromium resembles tungsten, and therein lies the chief analytical difficulty. The action of cupric ammonium chloride upon it was incomplete, and, indeed, no single treatment was found effective. 0.5 gm. of the ferro-chromium to be analysed is fused with either sodium nitrate or a mixture of 240 parts of sodium carbonate with 160 parts of potassium nitrate, or one of 4 parts of fused sodium chloride, 1 part of fused sodium carbonate, and 1 part of potassium chlorate.

Instead of this direct treatment it may be previously exhausted with hydrochloric acid, and the residue attacked with a fusion mixture. If the third fusion mixture be used, it is essential to continue the heating for a moderate time only, as prolonged heating decomposes the chromate first formed.

The melt is extracted with water, and the aqueous solution (containing chiefly the chromium) and the residue (containing chiefly the iron and manganese) analysed separately, or together. In the latter case the residue is dissolved in hydrochloric acid (any insoluble matter re-fused), and the solution added to the aqueous solution of the melt, care being taken to keep the whole acid. The mixture is evaporated to dryness, and heated to 120° C. for a quarter of an hour to separate silica, taken up by hydrochloric acid, filtered, and the residue ignited, weighed, and treated with hydrofluoric acid, giving the silica. Any tangible residue of oxides of iron and manganese is dissolved in hydrochloric acid precipitated by sodium carbonate, and re-fused with one of the above fluxes to make sure of the absence of chromium. The filtrate from the silica containing iron, manganese and chromium is treated by Reinhardt's process (Stahl und Eisen, 1889, 5; this Journal, 1889, 572), modified by the author, which is as follows:—

To the boiling solution is added sodium hypophosphite (200 gm.  $\text{NaH}_2\text{PO}_2$  in 400 cc. of water) in quantity sufficient to give a pure green solution without any shade of yellow, pure zinc oxide in suspension in water added while it is still hot, in slight excess, the precipitated chromium, together with the zinc oxide, filtered as quickly as possible, washed, re-dissolved, the reduction and precipitation repeated, the precipitate dissolved in hydrochloric acid, precipitated with ammonia in excess, the chromium hydrate (now nearly free from zinc) re-dissolved, and reprecipitated by a small excess of ammonia. The purity of the chromic oxide after ignition and weighing is proved by fusing it with the second fusion mixture mentioned above.

**Analysis of Chromium Steel.**—Chromium steel may be dissolved by cupric ammonium chloride, but such a mode of solution presents no advantages and contains many pitfalls. The author prefers to dissolve the steel in hydrochloric acid, separate the silica as usual, and the chromium from the iron and manganese by Reinhardt's method (see above). This has the incidental advantage that manganese may be determined in a portion of the same solution. Carbon is best estimated by burning the finely-divided metal in oxygen. If Eggert's test be used, a chromium steel must be taken as a standard, the chromium giving a more or less grey tone to the solution.

Some analytical hints for working these methods are collected at the end of the paper.

A small quantity of tungstic acid will sometimes remain undissolved on the filter through which the bulk has been

washed by ammonia; in this event the filter may be ignited, treated with hydrofluoric acid, and the residue weighed. Nitric acid does not separate silica perfectly, even by evaporation to dryness. Ignited tungstic acid is quite unaffected by heating with hydrofluoric acid, a practice that should be never omitted to eliminate silica. Hydrated tungstic acid is not quite insoluble in any acid, even nitric acid; hence excess should be avoided. Tungstic acid appears to be slightly soluble in silver nitrate. Seeing how refractory are the compounds of tungsten and chromium with iron and manganese (chrome iron ore will serve as a case in point), special watch should be kept over iron precipitates or residues obtained in analyses of alloys of these metals, and their freedom from the two former ascertained.

Ferrie tungstate appears to be somewhat soluble in ammonia under certain circumstances, for a little ferrie oxide often separates during the evaporation of an ammoniacal solution of tungstic acid obtained by the use of nitric acid. On drying commercial tungsten at 120° C. a loss of 0.37 per cent. was observed in one case. All work with solutions of chromium is best done by daylight. Ferro-silicon and ferro-aluminium are not attacked by fusing sodium nitrate sufficiently for analytical purposes.—B. B.

*Examination of a Method for the Determination of Tartar, Tartaric Acid and Malic Acid.* R. Gans. Zeits. f. angew. Chem. 1889, 669—670.

THE author has examined the working of the method given by Borgmann.

The method for determining the tartar is as follows:—50 cc. of wine are evaporated in a porcelain dish to a syrup with addition of a little quartz sand; after cooling about 70 cc. of 96 per cent. alcohol are added, the whole being kept well stirred. After standing in a cool place for 12 hours, filtration is performed, and the residue is washed with alcohol until the washings are no longer acid. The alcoholic filtrate serves for determination of the free tartaric acid. The filter is returned to the dish, hot water is added and the solution is run through a fresh filter paper. Extraction with hot water is repeated until the filtrate no longer shows an acid reaction. The solution is then titrated with decinormal caustic soda solution. For determination of the free tartaric acid, the alcoholic solution before mentioned is made up to a known volume and divided into two equal parts. One part is exactly neutralised with decinormal caustic potash solution; the two parts are then recombined and the alcohol is distilled off. The residue is evaporated to a syrup in a porcelain dish with a little quartz sand, and the determination carried out exactly as before.

The author states, with regard to the tartar determination, that in solutions containing large quantities of sugar part of the tartar is not precipitated by this method, whilst on the other hand part of the free tartaric acid refuses to be washed out from the syrupy mass. With regard to the tartaric acid determination, this is likewise not accurate, as a part of the tartar, not precipitated, and some of the potassium malate which has not dissolved, are estimated along with it; and again a small percentage of the tartaric acid remaining in the tartar residue is not determined in its proper place. If no sugar be present the results obtained are still worse, as almost the whole of the potassium malate separates and is determined as tartaric acid. From such considerations it is also evident that the method cannot be used for the determination of the malic acid present.—T. L. B.

*The Citrate Method of Determining Phosphoric Acid.* O. Reitmaier. Zeits. f. angew. Chem. 1889, 702—709.

FROM an exhaustive consideration of the various reactions which probably take place when phosphoric acid is precipitated from solutions containing oxides of manganese, calcium, iron, and aluminium, by means of magnesia mixture, the author draws the conclusion that a double citro-phosphate of ammonia and magnesia is invariably formed to a greater or lesser extent, and that the less the

excess of magnesia in the solution, the greater is the extent to which this salt is formed, and as a practical outcome he recommends that the more citric acid required to retain the oxides in solution the greater should be the excess of magnesia added above that required to unite with the phosphoric acid.—J. W. L.

*The Determination of Oxide of Iron and of Alumina in Crude Phosphates.* A. Stutzer. Zeits. f. angew. Chem. 1890, 43—44.

THE author points out that the method generally adopted of weighing the iron and alumina in crude phosphates in the form of a mixture of iron and aluminium phosphate, and taking the ferrie oxide and alumina as being equal to one-half of the total weight of the precipitate, is both unscientific and unsatisfactory. It is far better to separate the oxides from the phosphoric acid, and the following method has been found to work well:—The hydrochloric acid solution of the phosphate is made alkaline with ammonia, and then slightly acid with acetic acid. The residue, consisting of the phosphates of iron and alumina, is washed into a beaker, and treated with ammonium nitromolybdate. The precipitate is filtered off and the iron and alumina determined in the filtrate as hydrates. Any molybdic acid carried down by them is removed by redissolving in hydrochloric acid and reprecipitating.

—C. A. K.

*Rapid Methods for Testing Tallow and the Solid Fatty Substances offered as Substitutes for them.* H. Talfe. Bull. Soc. Chim. (3), 2, 209—210.

TALLOW contains its fatty acids combined as glycerides. Only minute quantities of these acids are to be discovered in the free state, owing to spontaneous decomposition or to the treatment of the crude fat whilst hot; the stearic acid serving for the manufacture of candles is on the contrary not in the combined state. The following method is used by the author for testing tallow and stearic acid. Five grms. of the fatty substance to be tested are treated in a capacious crucible with 10 cc. of pure olive oil and gently heated, a drop of turmeric solution added, and after cooling the mixture is titrated with caustic soda lye with continual shaking round. The free acid found is reckoned as stearic acid. In like manner, of course, the free acid in the oil employed for solution must be estimated, after mixing with double its volume of strong alcohol. The free acid in the oil is deducted in the estimation of the fat under examination. In olive oil 2.5 per cent., and in tallow candles 3.6 per cent. of free acid were found. In stearin candles of best quality 100 per cent. of stearic acid were found.

*Simple Process for Discovering Cotton-Seed Oil in Fats and in Olive Oil.* T. Leone. Gazz. Chim. 19, 1889, 355—357.

RECENTLY a process of adulteration has made its way into Italy by which fats of every kind are treated with cotton-seed oil and are made to acquire the taste and melting point of pig's fat. This sophistication can easily be recognised in the following way:—A few cc. of the suspected fat are introduced into a test tube, and an equal quantity of an acid alcoholic solution of silver nitrate added (1 per cent. of  $\text{AgNO}_3$  and 0.5 per cent.  $\text{HNO}_3$ ). The mixture is then warmed for 5 to 6 minutes on the water-bath. If the fat is adulterated there is formed at the point of contact of the two liquids a yellowish-brown ring, whereas in the opposite case, not the slightest colouration is perceptible. An addition of 5 per cent. of cotton-seed oil can thus be recognised with certainty. Similarly the presence of cotton-seed oil in olive oil may be detected.

*Optical Analysis of Oils and Butters.* E. H. Amagat and F. Jean. Compt. Rend. 109, 616—617.

THE oils are placed in a metallic cylinder with glass ends forming an angle of 107°. There is a suitable arrangement for maintaining the less fusible oils in a liquid condition.

The amount of refraction is observed in a special kind of spectrometer not essentially different from the ordinary form of this instrument.

It is found that there is considerable difference in the refractions of various kinds of oils, though the same kind of oil even when coming from different localities has practically the same refraction.

This method of examination is useful for the detection of certain adulterations, for instance, the addition of 10 per cent. oleomargarin to butter may be detected in this way.

—A. L. S.

*Analysis of Manures.* Zeits. f. angew. Chem. 1889, 690—691. (Compare this Journal, 1890, 115.)

THE following are the methods agreed on at a meeting of chemists from the various manure works of Germany:—

#### A. Preparation of the Samples in the Laboratory.—

1. Dry samples of phosphates and artificial manures require sieving and then mixing.

2. In cases of moist manures, a thorough mixing must suffice.

3. On receipt of the sample it must be weighed. Raw products must be sieved, then one-half finely powdered, and the remainder used, simply sieved, for determination of the moisture.

4. Samples should be kept for six months, for reference, stored in good bottles in a cool place.

5. The water of phosphates and bone charcoal must be determined at 105°—110°. Where samples give off ammonium carbonate, this must be determined also.

6. Samples sent for analysis should be fairly selected, should weigh about 500 grms., and should be packed in a bottle with good stopper.

#### B. Determination of Soluble Phosphoric Acid of Superphosphates.—

1. 10 or 20 grms. of the superphosphate are made into a paste with water, and introduced into a measuring flask. The flask is filled up to the containing mark with water, the whole well shaken, allowed to stand, and filtered.

2. The volume of the undissolved residue is here neglected.

3. Volumetric determination of the phosphoric acid is considered out of date.

4. Wagner's modification of the molybdenum method may be used.

5. The citrate method may be used, provided this agree with the results given by the molybdenum method. "Controls" may be performed by the last-named method only.

6. Moisture is to be determined in superphosphates by heating 10 grms. for three hours at 100°. Loss of weight is taken as due to moisture.

#### C. Determination of the Phosphoric Acid soluble in Citrate Solution.—

No conclusions arrived at.

#### D. Determination of the Insoluble Phosphoric Acid.—

1. For determination of the phosphoric acid in bone meal, fish-guano, flesh manures, phosphates, and of the total phosphoric acid in superphosphates, the sample is dissolved in *aqua regia* (3 parts of hydrochloric acid of sp. gr. 1.12 and 1 part of nitric acid of sp. gr. 1.25).

2. Slag powder is dissolved in hydrochloric acid, nitric acid being subsequently added.

#### E. Determination of Iron and Aluminium in Phosphates and Guano.—

The so-called "conventional method" is not to be relied on; the alcohol method (this Journal, 1890, 111) is recommended as worthy of trial.

#### F. Nitrogen Determinations.—

1. Nitrogen in blood, flesh, and similar organic substances is determined either by Kjeldahl's method or with soda lime.

2. Ammoniacal nitrogen is determined by Kjeldahl's method. If it is certain that no other nitrogenous compounds are present, distillation with 5 per cent. caustic soda, magnesia, or lime may be used.

3. The nitric nitrogen in mixtures is determined by the method of Schlösing and Grandean, Lunge, or Kjeldahl and Iodbauer. For determination of nitrogen in saltpetre a direct method is to be sought after; the methods of Kjeldahl and Iodbauer, Schlösing and Grandean, and Lunge (nitrometer method) are permissible.

#### G. Generalities.—

1. The value of phosphates, guano, bone-ash, and saltpetre must be reduced according to the moisture contained in the original sample.

2. Control analyses must never be performed with substance, part of which has been used in the previous analysis. Two reserve samples must be taken for the purpose.

—T. L. B.

*The Simultaneous Estimation of Carbon and Sulphur in Organic Sulphur Compounds.* L. Prunier. Compt. Rend. 109, 904—906.

THE substance to be analysed is mixed with 80—100 times its weight of pure powdered potassium permanganate. The mixture is introduced into a combustion tube and heated in a way similar to that when copper oxide is employed. The gases produced during combustion are allowed to bubble through a solution of potassium permanganate. The apparatus ends in a tube containing baryta water, which should not become turbid if the combustion be properly conducted. On the completion of the experiment, the contents of the tube are dissolved in water and filtered through asbestos to remove the insoluble manganese dioxide. The filtrate is mixed with the solution of permanganate from the bulbs. From half of the combined solutions the sulphuric acid is precipitated as barium sulphate in the usual way, the permanganate being previously destroyed by heating with hydrochloric acid. The other half of the solution is boiled with an excess of sulphuric acid and the carbon is completely converted into carbon dioxide, which may be estimated in the usual way by absorption in potash bulbs. The insoluble portion is treated in a similar manner, the quantity of carbon found being added to that found in the solution. Satisfactory results were obtained in the case of substances containing as much as 65 per cent. of sulphur. The analyses were made on bodies containing, besides carbon and sulphur, hydrogen and oxygen. It remains to be seen whether the method is applicable to nitrogenous bodies.

## New Books.

A DICTIONARY OF APPLIED CHEMISTRY. By T. E. THORPE, B.Sc., Ph.D., F.R.S., Treas. U.S., Professor of Chemistry in the Normal School of Science and Royal School of Mines, South Kensington. Assisted by eminent contributors. In three volumes. VOL. I. 1890. London: Longmans, Green, and Co.; and New York: 15, East 16th Street.

LARGE octavo volume, handsomely bound, price 42s., containing Preface by the Editor, list of Abbreviations of Titles of Journals and Books referred to in the Text, list of Contributors to Vol. I., and 715 pages of Subject-Matter. With the Text are interspersed some 222 well executed wood engravings. The last subject treated of in Vol. I. is "Dysodil," this being immediately preceded by the valuable

contribution on "Dyeing," the volume thus comprises the treatment of subjects extending from A to DY.

In the Preface Professor Thorpe, in an interesting paragraph, refers to the relative positions of Pure and Applied Chemistry, represented, as regards Pure Chemistry, by the new edition of Watts' Dictionary of Chemistry by Morley and Muir, to which, as he says, "the present work may be said to be complementary," and as regards Applied Chemistry, by his own Dictionary now under notice. He adds, "Although the two works are in a broad sense complementary, it is practically impossible to avoid a certain amount of overlapping, and therefore a certain degree of independence. Hence in the present work the chemical history of a product of technical importance, so far as it is known, has often been completed, although its derivatives have, at present, no applications in the Arts. Moreover, such subjects as the Atmosphere, Water, Fermentation, the Chemistry of the Hydrocarbons, the Vegeto-Alkaloids, Glucosides, &c., &c., all of which are dealt with in the other work, find also a place in this Dictionary by reason of their relations to Technology or to Medicine and Sanitation. In all cases, however, these subjects are treated from the standpoint of practical application." The list of the Names of Contributors and the selection of their subjects inspires confidence at once. Without desiring to attempt any comparison of the methods of treatment of the various articles dealt with in the text, or even of referring to all the specially able articles written, a brief extract of some of more immediate interest may be given. Following then the list of Contributors, the subject of *Cellulose* by its very subdivision suggests all that need be said of it. It is first considered physiologically and theoretically, and then a brief account follows of the action of Hydrolytic and Dehydrating agents upon the typical *Cellulose*. After this follows "Technical Application." Next we have enumerated and briefly described the reactions with various reagents, such as Alkalis, Chloride of Zinc, and Sulphuric Acid, leading again to various other *Technical Applications*. "*Oxy-cellulose*" is then treated of, and its relation to and distinction from *β-Oxy-cellulose* explained, and lastly the "*Constitution of Cellulose*" is given and a formula advanced.

The "*Physiology of the Compound Celluloses (Vegetable Fibres)*" is now discussed, and after this their chemistry is considered. These are classified for treatment as follows:—"*Adipocelluloses*" (the protective tissues of plants), the "*Pectocelluloses*," and the "*Lignocelluloses*." In the course of this treatment technical methods are given and some patented processes quoted.

The reader is thus led on to "*Chemical Processes for Disintegrating Wood*," and the article closes with Bibliographic references.

Under the heading of Benzene and its Homologues, a technological feature of special interest, is the engraving and description of Aders' Benzene rectifying apparatus of latest type.

The subject of *Cements* is subdivided as follows:—1. Building Cements. 2. Resinous Cements and Adhesive Materials. Under *Building Cements* we have 1. Lime Burning. 2. Mortar. 3. Plaster of Paris. 4. Hydraulic Mortar. 5. Pozzolana. 6. Hydraulic Cements. 7. Oxchloride Cements. 8. Artificial Stone. 9. Concrete. Specially divided paragraphs are devoted to the consideration of the Causes of Setting of the above Cements. Under Group II., Resinous Cements and Adhesive Materials are considered: 1. Resinous Cements. 2. Oleaginous Cements; and 3. Gummy and Gelatinous Cements.

If the mode of treatment of the subject of *Ammonia* be finally sketched the general arrangement and system of the work will be rendered tolerably clear, though several other subjects, the development of which is just as skillfully conceived, though necessarily more detailed and complex, might be given in abstract.

*Ammonia*.—General Conditions of Formation; Properties; Solubility; and Table by Lunge and Wiernik of Densities of Aqueous Solutions at 15°. *Technical Sources*.—A. Natural Occurrence of Ammoniacal Compounds. B. Ammonia made from Hydrogen and Atmospheric Nitrogen. C. Ammonia from Cyanides, prepared by Means of Atmospheric Nitrogen. D. Ammonia from Urine, Sewage, and

Animal Excreta. E. Ammonia from Guano, &c. F. Bones, Horn, Leather, and other Animal Substances rich in Nitrogen. G. Ammonia formed in Inorganic Chemical Manufactures. H. Ammonia as a By-product in the Manufacture of Beet-root Sugar. I. Ammonia from Peat and similar Matters. K. Ammonia from Bituminous Shale. L. Ammonia from Coal. The "*Working-up of Ammonia Liquors*" is next considered, and then are described, with the aid of engravings, the Ammonia Stills of Coffey, Mallet, Grünberg, Grünberg and Blum, and Feldmann. The manufacturing processes for Ammonium Chloride, Commercial Carbonate of Ammonia, and Caustic Ammonia are also described.

These examples will serve to indicate the general method of treatment and subdivision followed in the case of most of the subjects.

DIE CHEMIE DES STEINKOHLENTHEERS MIT BESONDERER BERÜCKSICHTIGUNG DER KÜNSTLICHEN ORGANISCHEN FARBSTOFFE, VON DR. GUSTAV SCHULTZ. Zweite vollständig umgearbeitete Auflage. Zweiter Band DIE FARBSTOFFE. Sechste Lieferung. Braunschweig: Friedrich Vieweg und Sohn. London: H. Grevel and Co., 33, King Street, Covent Garden. 1889.

THIS, the sixth part of the second volume of Dr. G. Schultz's well-known work on the "*Chemistry of Coal Tar with Special Reference to the Artificial Organic Colouring Matters*," is a simple continuation of the fifth part, without any Preface or other introduction, commencing with page 961 and closing on page 1152, though apparently not completing the work on that page.

The subject first taken up and continued is that of *Colouring Matters of Unknown Constitution*, amongst which *Phthalimide Blue* and the *Thiamine Group* are treated of. We then come to an Appendix containing a series of additions to the Subject-Matter of the preceding volumes, with references to those volumes and to the particular places therein where the additions should come. The larger proportion of these additions are abstracts of German patents, but wherever it has been possible the data have been gathered together and tabulated. This Appendix commences on page 969, and is still under treatment on the concluding page of the sixth part.

## Trade Report.

### TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

#### SWITZERLAND.

##### Classification of Animal Oil.

Note.—Quintal = 220·4 lb. avoirdupois. Franc = 9  $\frac{9}{10}$  d.

The following decision was given by the Swiss Customs authorities in December last:—

Animal oil (oil of hart-horn, bone oil) raw.—Category 259. Duty, 1 franc per quintal.

#### TURKEY.

##### The Importation of Pharmaceutical Specialities.

The *Journal de la Chambre de Commerce de Constantinople* for the 18th January last states that Colonel Rassim Bey, Inspector-in-Chief of Customs, has just applied the article of the law on the sale of medicines in Turkey,

according to which pharmaceutical specialities, the composition of which is not declared at the Imperial School of Medicine and approved by the council of that school, are not to be admitted into the Empire. Also, pharmaceutical products manufactured in the country, and of which the formula is not deposited with the council of the said school, will be confiscated.

#### UNITED STATES.

##### Recent Customs Decision.

So-called "acid stibic" or white oxide of antimony is dutiable as chemical salt at the rate of 25 per cent. *ad valorem* under T. I. 92.

#### ARGENTINE REPUBLIC.

##### New Customs Law for 1890.

A despatch, dated the 30th December, has been received at the Foreign Office from the Hon. F. J. Pakenham, Her Majesty's Minister at Buenos Ayres, enclosing two copies of the *Boletín Mensual* for November, in which is given the law (a translation of which is also enclosed) regulating the Customs duties for 1890. The following is taken from the translation in question:—

Art. 1. All merchandise from foreign countries shall pay an import duty of 25 per cent. on its value in bond, except the following articles, which shall pay: 50 per cent.:—Gunpowder for sporting purposes, ammunition, and perfumery. 45 per cent.:—Matches, other than wax. 10 per cent.:—Paper for writing and printing. 5 per cent.:—Coarse salt, sulphuric acid, and sulphate of lime, tin and lead plates.

Specific duties as follows:—

Articles.		Rates of Duty.	
		Dols.	Cts.
Starch .....	Per kilo.	0	07
Unrefined sugar.....	"	0	07
Refined sugar.....	"	0	09
Candles.....	"	0	15
Stearin .....	"	0	12
Wax matches .....	"	0	50
Paper, other than for writing or printing	"	0	12

The following articles shall be free of duty:—

Quicksilver, crude sulphur, dynamite, and vegetable fibre for manufacture of paper.

All kinds of produce and manufactures of the country are free of export duties.

#### CANADA.

##### Addition to Customs Free List.

Sulphate of soda, crude only, and for manufacturing purposes only.

## EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

#### JAPAN.

##### Oil Colours.

These articles are purchased exclusively in England, there being no German competition at present. The demand is extending from year to year, yellow, red, and white being the most popular colours.

#### Drugs and Chemicals.

The total import of drugs and chemicals in 1888 was valued at 1,645,875 yen, of which 956,567 yen were imported into Yokohama. The bulk of these articles are of German origin. All medicinal goods before reaching the Japanese public must be stamped with the words "Fit for medical use," and pass a special board of examiners. Since the beginning of 1888, however, only such preparations as have been prepared according to the instructions of the Pharmacopœia Japonica are admissible. This Japanese Pharmacopœia is issued in Latin and in the vernacular, and modelled very closely upon the German one. The Japanese pharmaceutical industry is hardly yet sufficiently advanced to offer any serious competition to foreign importers. The only Japanese pharmaceutical preparations which have almost completely ousted foreign-made goods from the market are phosphorus, sulphur, sulphuric acid, and nitrate of silver. For the rest no native competition need be feared for at least some years to come; in fact, European medicine being more and more popularised in Japan, the prospects are that this branch of trade will still develop considerably. The following observations refer to the principal drugs sold on the Japanese market:—The demand for boric acid has fallen off; in 1887 the consumption in Yokohama amounted to about 1,000 lb. per month; in 1888 to only about 800 lb. Carbolic acid continues to be bought exclusively in England, but salicylic preparations, another article of great importance, come mostly from Germany. Salicylic acid is principally used in Japan for preserving saké, the national beverage, prepared from rice. The best way to import salicylic acid is to pack it in tin or cardboard boxes, as the local dealers like to put it up in their own vials. The consumption of alcohol is increasing. It is bought in Germany and America, and is packed in kegs. The manufacture of sulphuric ether is about to be taken up in Japan. The trade in atropine has almost entirely gone into British hands during the last few years. German atropine has been frequently objected to by the Japanese authorities on account of its bad quality. Similar objections have been made to bi-muth, which was formerly also bought almost exclusively in Germany. Chloroform finds a regular market in parcels of 500 lb. at the time, but the demand has fallen off owing to the increase in the consumption of cocaine, which is generally sold in 1-grain vials. In quinine Pelletier's brand continues to be popular, but during 1888 German brands have for the first time made themselves seriously felt on the market. Antipyrin and antifebrin are becoming very popular. Iodine preparations come mostly from Germany, but nearly all the morphia used is English. The demand for santaline has declined, but that for pilocarpine in 1-grain vials is slightly on the increase. The use of tannin is increasing in medicine as well as for dyeing purposes. Crystals are almost exclusively used. Caustic soda is becoming an article of importance, owing to the growth of the local soap and paper-making industries. It has hitherto been imported exclusively from England in 500 lb. to 600 lb. iron drums. The following figures refer to the quantities of some of the principal drugs imported into Yokohama in 1888:—Alum, 549,233 cattie; bromide of potassium, 20,146 cattie; quinine, 64,765 oz.; morphia, 5,966 oz.; gum arabic, 40,376 cattie; glycerin, 61,649 cattie; iodide of potassium, 18,598 cattie; carbolic acid, 52,371 cattie; cinchona bark, 41,041 cattie; salicylic acid, 7,701 cattie; amorphous phosphorus, 8,236 cattie; santaline, 3,600 cattie; bicarbonate of soda, 1,397,577 cattie; caustic and crystal soda, 2,653,275 cattie; various drugs and pharmaceutical articles, 545,000 yen; dyestuffs, 816,000 yen; oils, 1,743,000 yen.

#### Japan Wax.

The preparation of vegetable wax is one of the principal industries of the island of Kiu Siu. The wax is gathered in the most primitive manner from the berries of the *Rhus succedanea* (Hazenoki tree). In some districts hydraulic presses have been introduced for its preparation, but the result has not been satisfactory. The best wax is produced in Kummamoto, but does not appear in commerce, as it is all sent to the Imperial Court. The best commercial

wax is made in the province of Iizen, and brought into commerce *via* Osaka. The traders in that place are better capable of purifying and bleaching the wax than the peasants in Kin Sin. In Japan the wax is largely used for candles and in the preparation of hair ointment.

#### PORTUGUESE COLONIES.

##### *Export Duties in Mozambique.*

An export duty is levied on nearly all goods shipped from Mozambique, and this duty, in the case of some articles, such as ivory, is so heavy, as to operate considerably against any expansion of trade. Calumba root and oil seeds, however, only pay 1 per cent.; orchella and gums, 2 per cent., and beeswax 5 per cent. *ad valorem*.

#### SPAIN.

##### *Cream of Tartar.*

In his report on agriculture in Catalonia and Valencia the British Consul at Barcelona states that the plague of phylloxera is increasing at an alarming rate in these provinces, and it is now reported that proprietors are almost decided to cut down their vine plants to the ground with the hope of saving them. This would also injuriously affect the interests of the cream-of-tartar manufacturers, as there will be no wine lees, which is used in its production; these manufacturers are, therefore, getting up a petition to the Government to remove, for the time being, the duty on the importation of French wine lees, otherwise they will have to close their factories.

##### *Olive Oil in Malaga.*

The consumption duties on olive oil are so heavy that Spanish olive oil is actually sold in England at more than 1*l.* a lb. cheaper than in Malaga. Various mercantile associations continue to petition the Government for the abolition or reduction of these duties, but with little or no success.

It is to be regretted that no satisfactory method for refining the oil has ever been put into operation, because, owing to the want of such a system, after the oil extracted from the first pressure the remaining large quantities are used for lubricating machinery or lighting purposes.

#### STRAITS SETTLEMENTS.

##### *Drug Cultivation.*

At the Botanic Gardens in Penang they are hard at work experimenting with the propagation of economic plants. Castor-oil seeds were obtained from the Botanic Gardens at Calcutta. The plants have grown vigorously and are now commencing to fruit. Croton oil grows freely and fruits abundantly. Amatto also grows vigorously and is deserving of a trial on a large scale. Cubebs promise well, and are being propagated as largely as possible.

#### VENEZUELA.

##### *Cocoa-nut Oil and Tonquin Beans.*

The manufacture of cocoa-nut oil has recently been commenced in Venezuela by a Frenchman, M. Boissellier, who has opened a factory at Cumana. Tonquin beans are principally collected in the forest region of the Upper Orinoco Valley, where the bulk of the divi-divi and india-rubber exported from the country are also gathered. These forests are exploited by the Compagnie Française du Haut Orénoque. The principal trade centre for these products is Ciudad Bolivar, to where the goods are carried by the Orinoco steamers.—*Chemist and Druggist*.

## MISCELLANEOUS TRADE NOTICES.

#### PRODUCTION OF SALT IN GERMANY.

The French Ambassador at Berlin says, in a recent report, that a statement has recently been issued by the German Government on the subject of the production of salt works in Germany.

From this statement it appears that in the year 1888-89 there were produced in the Empire, 15,934 tons of crystallised salt, 342,596 tons of rock-salt not crystallised, and 516,521 tons of salt produced by evaporation, the two last qualities showing an increase on the average of the last 10 years. Crystallised salt comes from the Prussian province of Saxony, rock-salt from Wurtemberg, from the province of Saxony, from Anhalt, and from Posen. The salt produced by distillation comes from the provinces of Saxony, Hanover, Alsace-Lorraine, and Thuringia.

In the course of the year 1888-89, 734,623 tons of native salt have been disposed of for the home trade, of which 349,715 tons intended for food have paid the tax of 12 marks per 100 kilos., and 384,908 tons, utilised by industry and agriculture, have been exempt from any duty.

Exports reached 134,171 tons, distributed as follows:—30,212 tons for Bremen, Hamburg, and the other parts of the Empire not included in the Zollverein; 24,567 tons to Austria-Hungary, 19,638 tons to Belgium, 19,107 tons to Holland, 10,514 tons to Russia, 6,534 tons to Denmark, 6,504 tons to Sweden and Norway, 6,444 tons to the British Indies, 5,100 tons to England.

Exported salt does not pay any duty.

Imports were 28,057 tons, of which 25,265 tons were of British origin.

Foreign salt introduced through the ports pays an import duty equal to the tax. That imported by land routes pays 12·80 marks per 100 kilos.

The average consumption is 7·8 kilos. per inhabitant in the whole Zollverein.—*Board of Trade Journal*.

#### SALES OF QUININE IN HOLLAND.

According to the official Dutch notices, the public sales of quinine bark will take place at Amsterdam, during the present year, on the following days:—February 20, March 27, May 1, June 5, July 10, August 28, October 2, November 6, and December 11. The comparison between the results of the sales which took place in 1888 and 1889 shows a considerable increase in favour of the latter year. In the course of 1889 there have been sold 2,073,921 kilos., as against 1,435,047 kilos. in 1888. The State cultivation during the two years was nearly identical, but there was an immense increase in the amount grown by private proprietors in Java. The average of sulphate of quinine in the bark manufactured was 4·12 per cent.—*Ibid*.

#### INDIGO PRODUCTION IN WEST AFRICA.\*

The following information is contained in a letter addressed by Sir Alfred Moloney, Governor of Lagos, to the Secretary of the Liverpool Chamber of Commerce:—

"In Western Africa the indigo industry is, I may say, almost entirely confined to women, and is co-extensive with the cotton manufactured by the natives. Its range may be gauged when we remember the millions of cotton cloths that are there turned out annually for home consumption and export from the crude hand-loom of the country. The cloth export in the direction of Brazil is of special interest and of growing importance; their use has become a fashion there, where such cloths are employed for decorative and other purposes.
